Patent are confusing. Many of them are totally bogus. It's difficult to recognize the difference. However, at the bottom of every garbage dumpster lies a diamond. You have to sift through a huge amount of garbage in order to find the gem, but it's worth it. Just because a typical patent search returns bogus patents, doesn't mean you should ignore them. Most technical patents are legitimate and worth inspecting. If you want to know exactly how something works, the patents are the place to start. I haven't had time to look at the quantum comb filter antenna thing, but plan to do so eventually.

During the dot.com heyday, I was doing sanity checks and technological assessments for a venture capitalist. Many business plans had technical problems. Some were based on bogus patents. Some held conflicting patents. Identifying these was more than the VC's staff could handle. I did fairly well, but still managed to miss a few. Anyway, sifting through patents was part of the exercise and a great learning experience. Often, a patent looks legitimate, but has a fatal flaw or omission in the middle of the claims. It's not easy. If you have the patience, it's possible to find these.

Also, I assembled a small list of tech patents that appear to be bogus. I was going to post the list on the web but my attorney advised against it. Even holders of bogus patents can sue for damages. Oh well.

Yep. Also the bottom of the 1296MHz band went to GPS because hams
couldn't do anything useful with it. Also most of the 220MHz band
went to ACSSB and inland waterways because it was under-utilized and
because the ARRL couldn't get it together on no-code licensing. We
almost lost the 2.4GHz band because the ARRL was going to demand
priority over unlicensed wi-fi operation, but that was averted when
the ARRL directors received a rare dose of common sense from unknown
sources.

Unfortunately, the common justification these days is that ham radio
is a service hobby. When was the last time that ham radio advanced
the state of the art? I have some examples, but they're sufficiently
obscure that none would be sufficient to justify ham radios continued
existence. There is some logic in using the ham bands as a proving
ground for new technologies. Metricom did exactly that, but rapidly
switched to commerical operation. It seems that such advanced
experimentation is discouraged by Part 97. Most of the progress today
is in HF digital modes. These have their own sub-bands by convention.
Also QRP operation, spacecom, CW, and weak signal sub-bands. Various
nets also operate on specific frequencies. It wouldn't be much of a
stretch to unofficially allocate a sub-band to the technically
challenged, such as the old Novice class sub-bands.

Personally, I've suggested that CB'ers and Free Banders be issued
complimentary ham licenses for 10 meters and let them fight it out.
I'll be betting that the CB'ers win. Most of the "new hams" these
days are former CB'ers. With a few notable exceptions, most are quite
nice, but also technically lacking.

Tom but I have put in terms of the layman so that should be paradise
to those skilled in mathematicWhen the good Doctor
frm MIT provided the mathemartic showing the correctness of logic I
proposed with respect to Gauss and Maxwellk
mathematics as a route of viability was rejected by all. That really

needs exposure to the group as it is the foundation of radiation.
The computor is a wonderful thing but if an arrow is pointed in the
wrong direction it then becmes useless.
Nearly finished the mowing

Funding is easy these days. All you need is an anti-terrorism or
disaster link. For example:
- Use of HF antennas for airport security.
- Antenna design optimized for disaster services.
- Survivable antenna design and construction.
While these topics are contrived, there has been considerable
rethinking of the basics in order to enhance survivability, tampering,
security, terrorist activities, general mayhem, and other post-911
buzzwords. I'm not sure this extends to basic concepts, but it's
possible. Something like:
- Re-evaluating E-M concepts in a post 911 world.
- Survey of antenna technology for optimum disaster communications.

You will need to use your imagination because all the obvious studies
have already been taken. Perhaps combining everything into:
- The effects of global warming, terrorism, economic collapse, and
natural disasters on antenna technology.
Try to emphasize the positive aspects such as the improved HF antenna
grounding provided by rising sea levels.

Yer crocked! 1296 is fully utilized here and so was 220. People like YOU
who underutilized it and TOLD everyone it was underutilized are to blame for
US losing it!! Did you get a Ham license just so you could use 802.11/g on
channel 13?

Jeff you are a man after my own heart in your phillosophy . If I had
you
exposure of mathematics to replace what I have lost I would instantly
do what the good doctor did
and show the correllation of Maxwells laws to those of Gaussian static
laws when made dynamic
ie the addition of a radiator and a time varying field inside the
existing arbitrary boundary.
What the doctor showed has been totally rejected by this group without
I might had evidence to the contrary
Just....well....because. This is a throw back to the initiation of
mathematics where the Universe is founded on Equilibrium.

A pendulum when made long enough becomes sensative to changes in equilibrium in a similar way to the action of a super conductor Mathematics started with a balance exhib iting the ultimate of equilibrium and the mathematician invented "nothing" by placing both weights on one side
of a fulcrum. The long pendulum shows that sdame point when an eclipse occurrs where the equilibrium is momentarily disturbed as its boundaries are momentarily severed. Now we are pushing those same limits with superconductivity where laws such as V =IR become unmathomabble.
It is the same with antennas where all can realize that equilibrium tho fragile with respect to the term stable will provide maximum radiation but without resistance it is an imaginary term. Quadratics shows two terms show up where one is imaginary ala zero resistance so one moves to the other answer
anti resonance which is high knowing at the same time one can extend the length of the wire(number of periods) to produce the sensitivity of the extra
long pendulum which in mathematics follows the same laws. I use that same thinking because it is part of a universal laws. Thus I extend the length of wire used and at the same time balance the winding directions such that lumped loads are added such that the impedance and thus resonance goes down
as the number of wavelength goes up. Now I apply that same arrangement to antenna programs that have free reign to modify the arrangement according to the laws of Maxell based on equilibrium and the final version of the four forces plus the particles ala the standard model. The computor program which is designed around the standard model which was modified to suit the present planar antenna of today is overjoyed for being used for its initial use confirmes the arrangement produces above. As a check the same arrangement is supplied to a nec4 set up controlled by a academic and it againl passed the check.
Equilibrium cannot be discarded and all of the masters stipulate that as the founding condition, yet the present world has rejected it in favour of a computor
Shame Shame Shame. Now I finish off the mowing

You have wine? Why didn't you say so, that changes everything:

1) Put antennas away.

2) Have a glass of wine and contemplate the design/construction.

3) Repeat 2) until ALL wine is gone.

4) Take a nap.

5) Now get the antenna(s) back out and begin work ... LOL

JS
Mathematics is founded on the proposition of zero means nothing ONLY
if you ignore the presence of the weak force.
Thus mathematic has contaminated that which is the "equal" sign which
then is misused without the assumption of the underlying condition
You can cancell the effects of gravity but it is a lot different to
canceling the weak force.
Put scales on a bench to oppose gravity does nothing to neutralise the
weak force
Thus in mathematics you can obtain negative answers which is the
measure of the weak force which is contradictory
to the "term" nothing in celestial terms but possibly is O.K. in
polotics
The CERN project is based on the collision of particles of the same
polarity but without the constraints of sideways movement
but the electron is much smaller than the area taken by an electron so
to my mind there is no collision only contra or lamina
flow UNLESs the particles are of different polarities which some
theorise as equating to the big bang.!

I have been accused often in the using of the wrong term
In the case of Newtons law as action creates reaction or similar.
Then somebody mentioned the law of parity which I considered as being
on par with what Newton said
Now another poster mentioned that parity described a farming practice
which also featured the pursuit of balance and parity
with respect to prices. Thus when the term parity was used I thought
that was a regrinding of the english language which I am now exposed
to.
I now remove the association of parity in the Laws as stated by Newton
who lived in the UK and not in the USA.

JS You know the saying that when one door closes another opens.
In my case starvation of oxogen to the brain was momentary such that
only the lines of communication
withered. Thus nothing was left to provide communication between the
different store houses of knowledge.
Due to experience the lines of communication of most people reflect
the motorways of New youk where the accumulation of intersections
allow misdirection of communication or the memory of where one was
originally going! Over a period of years where I concentrated on
antennas
as a method of rehab those missing communication lines were re
generated in reflection of my new experience as one would measure the
power of the growth of a babies brain. Thus my concentration on a
niche form of study is not impaired by the traffic jams of the past
which are now just decaying wreckage. Maybe the same is happening with
Hawkings. Ofcouse that leaves an opening for Dave that the decay
extended to the store houses of knowledge! My goodness isn't this
thread getting deep?
Best regards
Art

Yep. Newton's Laws of Motion are different on this side of the pond.

1. A particle will stay at rest or continue at a constant velocity
unless acted upon by revisionist politics, traffic laws, zoning
restrictions, local ordinances, or erroneous navigation information.

2. The net force on anything is equal to size of the politically
motivated masses multiplied by the sum total their campaign
contributions.

3. Every action has an equally reactionary opposition.

Jeff if you have everything placed before you your enthuseasm will
wain.
There is nothing wrong in exactly following in MY footsteps you have
your own
bag of choices by not being a follower which enables you to challenge
each step of logic.
Fortunately in my case it was the foundation on which I built that was
the subject of
challengr despite evidence opresented to the contrary The foundation
upon which everything rest
is that the supposition of making Gaussian law of statics equal to the
dynamic field of Maxwell only requires the addition of a radiator

and a time varying field such that both are equal in physical and mathematical form, from which point the details offered provide all the relavent points of logic.
This group mainly of electrical engineers have been brought up on the idea that statics are totally divorced from the mechanics of the electrical curriculum
to the rejection of particle mechanics and towards the idea that sciences all have diifferent laws to each other. Scientists understand this but authors
have not got to the stage of placing those findings in books which are initially provided by followers of science in the hope that some will carry the flag forward instead of concentration on the accumulation of wealth. If they can't read it in a book then it is not believable the same way as a scientific paper will not be accepted that do not
prevail on previous thoughts. Initial thought is thus rejected by the education of today. Academia will never accept anything
that is not received approval from their peers.
Thus without dragging them forcibly into the acception of change no change will occur., where as, your expertise in mathematics can test the logic to its limits which defy opposition
Best regards

>channel 13?

Been licensed since about 1964. There was about a 7 year period where
I let my license lapse. Hmmm... I should probably let it lapse again
as I was profitable, happy, and optimistic during those 7 years.

About 8 ago, I setup several scanners and a computah to run long term
statistics on channel utiliziation for a variety of services. For
fun, I threw in some local VHF and UHF repeaters. For 14 daytime
hours (I used 6am to 8pm) median utilization on public safety
frequencies ran about 20%. Somewhat less for various shared
commerical repeaters. However, of the 5 or so ham repeaters I
monitored, utilization was well below 1% (less than 1.5hrs per day). I
didn't bother to do any 1.2GHz repeaters, but I'll guess from one that
I have in my scanner, it's probably even lower. I had no way to count
users per channel per day, but if I did it manually, I suspect ham
radio would also be scraping bottom. Many ham repeaters have only one
user.

For what it's worth, I consider myself party responsible for educating
at least one ARRL director on the realities of the FCC balancing the
300 million wi-fi users against perhaps a handfull of hams on 2.4GHz.

I don't use Channel 13 for Wi-Fi. It's an unlucky number (and not
legal in the US).

Guilty as charged. If I can't be a part of the solution, I'll become part of the problem.

Incidentally, the LearnByDestroying.com has nothing to do with ham radio. A college I attended has the motto "Learn by Doing". <http://en.wikipedia.org/wiki/California_Polytechnic_State_University> That morphed into "Learn By Destroying" which seemed to be the practice in the engineering department. Since graduating with a rather substantial damage fee, I have adopted it as my personal motto. If you haven't destroyed and later repaired it, you don't understand how it works.

Incidentally, one of the tricks I learned (the hard way) was to
replace the mobile whip antenna with a piece of copper electrical
wire. Then cut it to length, tune, optimize, test and whatever. Once
the optimum length is established, replace the copper wire antenna
with the real stainless whip, cut to the exact same length.

>You have wine? Why didn't you say so, that changes everything:

The antenna transfer function of wine is highly exponential and very
non-linear. A little wine will produce a superior antenna. However,
incremental increases in wine dosage will tend to have lesser effects.
At some threshold, additional can cause a substantial drop in
performance. It may even go negative. Think equilibrium.

>Or, to summarize, the more complex the antenna, the more meters you are
>going to need ... LOL

Kinda reminds me of a former tech. All day, he would spend his time
working with the latest state of the art test equipment in the lab.
After hours, he would drag out his ham radio, and tune the xmitter to
maximum using a light bulb dummy load. Attempts to convince him that
the company test equipment might be useful for dealing with his radios
were futile.

>If away from my laptop, the programmable calculator is always in my
>pocket! (I mean, my gawd man, I have space invaders on it!) <straight-face>

That doesn't leave much room for the pocket protector. I collect HP
calculators. There are numerous calculators scattered around the
office and house. No need to drag a calculator around.

>... some patents are NOT what they used to be ... but then, there has

thats why they put those plastic plugs on elements, to keep the magical mystery dielectric particles from falling off instead of going back up the middle... if you ever lose the plastic caps you will notice the antenna starts leaking and the particles pileup in your yard making a real mess.

Jeff we all make mistakes by over estimating ones ability
In making one of my antennas I made a last minuit change just in time
before I finished the antenna
It was some weeks before that antenna was tested on the air in
Australia
That test proved that reprocity with respect to radiation is not a
given!.
I had neutralised the weak force such that particles could arrive but
not depart!
Yes it was an error on my part but it didn't rule out the value of
experimentationj.
Has anybody got a use for such an antenna?. This error in many ways
provided
proof that the trail I followed was coirrect. This is why I have
delayed the sending of a antenna to AC6XG
as the correction took over some of my free time. But Jim understands
what happened not necessarily why.
as he does have trust and an open mind as well as my respect.
When I supplied an antenna to the U of I I gave them a sample of the
same antenna in Australia
because of their treatment towards me and comments made in advance of
getting the antenna.
Thus I gave them exactly what they expected to get based on pre
examine comments similar to those of this group
He who laughs last laughs longer and forever. Something like getting a
bunch of wire with lip stick all over it
Best regards
Art Unwin....KB9MZ.......xg

If the inside is covered with an eddy current field the particle
cannot get to the aluminum
which debunks the idea that the electron can penetrate evreything.
Forgeting the fact that it is searching for a
diamagnetic surface to rest upon. The same situyation is repeated
inside a wave guide.
Do you think I could put "Doc' with my name to impress people?

Now let me analyze this and see ...

1) He is dealing with matters/effects/theories/speculations which
universities/physicists/scholars/mathematician/theorists/amateurs/etc.
are working/speculating/experimenting on.

2) Usually actions/effects/affects/phenomenon are observed before it
even occurs to anyone to design an equation or formula about it.

3) Some speculations will, obviously, be incorrect or partially correct
and need rethinking, or scraped and new ones advanced.

4) Etc., etc.

Nope, you are quite correct ... he hasn't. However, to some, the
reason(s) will be quite obvious; for others, it may take a bit longer ...

Oh David emotion has got such a hold on you that you can't think
straight.
In one of the management classes I took they said if an employee can
not be calmed
always protect the path to exit. Medics say that anger or emotion can
shut down the route
to the house of logic in the human brain such that logic cannot come
into being.
Seams like the human brain is subdivided into physical block of
knoweledge
This explains why a baby learnes to walk quicker than a grown man with
experience
and tangled information routes.. You need a 2 by 4 to shake things up
Think about that Dave
Still your friend
Art

From Collaborative International Dictionary of English v.0.48 :

1. Containing nothing; not holding or having anything within;
void of contents or appropriate contents; not filled; --
said of an inclosure, or a container, as a box, room,
house, etc.; as, an empty chest, room, purse, or pitcher;
an empty stomach; empty shackles.
[1913 Webster]

A. I see no induication that the word has changed since at least 1913.
I see no indication of the use of "empty" as a scientific term that
includes absence of space.

B. It is obvious from the above definition that "empty" includes the
presence of space, otherwise there would be no locus of points which
could be characterized as empty. Another way to say it is, in the
absence of space, there is nothing to be empty. Without space, the
word "empty" has no utility or purpose.

Oops. Wrong Cal Poly:
<http://en.wikipedia.org/wiki/California_State_Polytechnic_University,_Pomona>
The San Luis Obispo motto of "Discere Faciendo" which is Latin for "To
Learn by Doing" was once the motto for both skools. The motto and
seal for Pomona changed when the skools split in the 1960's to
"Instrumentum Disciplinae" which is Latin for "Application of
Knowledge". This was often incorrectly interpreted as "Instrument of
Discipline" as indicated by the hammer and mace like weapons in the
logos.

in 1913 the study of particles was not linked to the four forces of
the standard model
It hasn,t hit the books because there is no series of references that
can be included.
No book no need for a revised dictionary no need for change

Ok, let's test your logic. So far, I've seen exactly one prediction of yours worth testing. It's you claim that current flows primarily in the center of a conductor. Avoiding the math for now, let's do the necessary thought experiments. If this were a court of law, the judge would prepare a set of rhetorical questions, all of which must be true if the plaintiffs claims were true. I'll do the same.

1. If current flows along the inside of a wire, and not on the outside, how does the field radiate through the alleged non-conducting outer part of the wires? The radiation would be trapped inside the conductor, only to perhaps emerge at ends.

2. If current flow along the inside of a wire, then it would seem that increasing the effective diameter of the conductor would have no effect on its impedance. Measurements of the Q of large diameter conductors versus small diameter conductors have show that impedance goes down with an increase in wire diameter.

3. How does a cage antenna work? The effective diameter is huge, but there's a giant hole in the middle, through which no current is conducted. If most of the RF current flowed through the center, and there is no center, then a cage antenna can't work.

I can conjur a few more rhetorical questions, but these should be sufficient to illustrate the problem. Your antenna current distribution model does not fit very well with tested reality.

Got any more prediction? I need the target practice.

I guess the word "empty" has no meaning anymore. Why, an astronaut in space cannot even carry an empty bucket. I'm sure you would agree that we should just strike the word from the Webster and Oxford dictionaries because you, who are immersed in advanced scientific thought, are convinced that a state of emptiness anywhere in the universe is impossible. I am truly humbled by your profound reasoning which I know would not be possible without that little extra touch of senility that releases you from the confining boundaries of logic. I assume that the absence of a correction by Mr. Cecil will indicate his agreement with your tripe. I might also mention that you need not reach out to Mr. Cecil to validate your bizzare pronouncements. Get some self-confidence in your statements Johhny, grow a spine!

Answer
Not so a length of radiator which is a fractional wavelenth will have
charges in motion on the outside creating radiation
the rest of the charge length will be inside the radiator where a
magnetic field cannot be created and particles if they were present
cannot pierce the eddy current on the surface. For radiation at all
times the radiator must be a wavelength or multiple thereof or a
period of the frequency in use for radiation to not disappear from the
surface where the levitating force is present to eject particles

Answer
Not so. the increase in diameter does not affect conditions that are
exposed to air
thus the progression of skin depth is the same. Thus copper losses on
the inside circuit
will be reduced as well as lost radiation resistance in the circuit. I
previously stated that

copper losses on the inside of a fractional wavelength antenna must be
considered separately from the groundplain resistance
which is required i.e. they are two separate resistances in series.

I am not familiar with a cage antenna but from the above description
is
that it is transformed into a Farady cage

Answer
>
> I can conjur a few more rhetorical questions, but these should be
> sufficient to illustrate the problem. Your antenna current
> distribution model does not fit very well with tested reality.

Hmm why not?
>
> Got any more prediction? I need the target practice.
Yes
Earlier I pointed to the fact that eddy current can be neutralised
such that particles canot be ejected from the surface
Indeependent testing showed there was nothing to prevent particles
from settling on a diamagnetic substance thereby inducing
an oscillation . At the same time on the transmitting side the
particles were still present on the diamagnetic surface because the
ejection force
was neutralised thus preventing ejection otherwise seen as
transmission.

Another one
The computor on the first example disapointed me as I expected a
higher gain (stated on this net)When I corrected the nullification of
the foucault current by separation the computor program gave the gain
I initiall expected in gun shot form which migrates in a way to a
lazer ray which is oif a similar science
thus HF does not necessarily have to diverge such that gain is
nullified.

If you want more target to aim at listen for the BIG BANG and then aim
at the resulting BLACK HOLE

Now I see where you are getting all this sci-fi. Finally. You mistake a philosophical, abstract ether with the type of physical ether being inferred in this thread, i.e. the ether that was banished from normal scientific thought by Einstein in 1905 after publishing the Special Theory. Kostro is not a scientist, he is a Philosopher of Science who longs for the old ether concept (I would suppose to assist in his understanding of the universe) and who claims Einstein really did believe in a revised concept of ether after 195 or so...no way. He did not, as a physicist. As a philosopher, for him anything was possible, even a unified theory. But there is no ether variable or constant that must be present in order for the relativity calculations to work. It is the job of a philosopher to analyse these parameters, real or imagined, and remind us that those concepts we threw over the fence decades ago MAY still have validity. Philosophically this is true if in your mind experiments you think there actually may be a connection between light and an ether medium. But philosophy does not show up in the math. Kostro correctly states that Einstein himself did not completely dismiss this notion but that is far cry from resurrecting another century of ether theory. Nice try Johnny boy.

Here is another on per Newton for stabalization ech action has an
opposite
reaction. I have pointed to the construct to represent these two
forces where the
rotators are at right angles to each other as with the Foucault
current.
On a terrstial scale tidal forces must also produce eddy currents of
circulating water.
Such large areas have beem found lately of the coast of Spain which is
now widening the search
rather than relying on idle reports from shipping. Since weather is
also in terrestial form a storm force
by definition requires the same force for stabalisation thus the whirl
pool and the tornado. Note the reaction force is sometimes swamped by
the
providing force by paramagnetic effects tho with respect to tornadoes
droplets of water as well as the particles at rest are drawn up into
the sky where water as a diamagnetic material provides a shift in
energy of a static form. Jeff everything seems to mesh with what I am
disclosing In addition when the droplets of water gets colder and
turns to ice the resident particles are forced to find a new home and
gyrate towards water which trees and humans consist of. The contained
energy of such particles is so small that it is inconseivable that
serch for a new resting place would contain energy of stellar size
but the movement of such particles at a high speed would provide
harmonic motion to the particles to generate a swarth of different
frequencies.
And it gos on and on
Art

Added observation
In the UK it is not unusual after a storm to find isolated patches of
frogs etc far from their normal habitat
A frog consists mainly of water upon which the surface is covered with
particles such that the frog is drawn up
in the Newton cycle. Unfortunately the frog does not freeze such that
the particles need to move away.
Unfortunately the frog falls a long way back to the ground again. The

same thing has happened with fish and frogspawn
after a storm

Another prediction
Particles are known to collect in bunches where the bunch contains
three basic electrons
bound together by the force of colour which is known to be very strong
Ofcourse not all
of the particles bunch together as previously stated. When the color
bound bunch of electrons
come into contact with a strong magnetic field, the strongest being at

the poles the electons are torn apart releasing
the binding energy in a aurora that spreads for thousands of miles. In
the case of a lazer on can imagine that that same particle
is similar to others but with the vestiges of color and we know that
the energy emmitted dose not fan out giving strength to my antenna
which also
gravitate to a non spreading relation ship.
And it goes on and on and..

Seeing as you are trying to stop RF, using copper tape / foil and copper screens / expanded sheet metal / densely perforated sheet metal is the best bet for shielding approaches. Very large ferrites for creating chokes (high motor currents). Try very large snap on ferrites around the lead groups entering and exiting the Magnetek. Both on individual leads and on three / (four ?) / six lead groups headed to the motor.

> And it gos on and on
> Art

It is argued that emmisission from the Sun consist of Leptons which
have different flavours
I submit that what you are seing is neutrinos which by virture of the
coupling forces with other neutrinos which generate different
"flavours"
Some bunches provide a coupling force and thus produces what is termed
a coupling force of three primary colors
Tho arora is a result of separation there is noo reason to believe

that only single particles make it to earth even tho colour is
distincly ly a part of polar aurora. In the case of light or lazer
ejection the final color depends on the coupling between neutros and
the primary color binding thst they posses
Thus lepton are nothing but smoke equivalentsin single or different
bunching form which while the sun is burning will continue to be
emitted by the sun as the arbitrary boundary expands and release
particles to re attain equilibrium. When a eruption occurrs within the
sun occurrs the escaping particles also include particles of a 100
percent energy with respect to life of the particle. It is when such
erruptions occur local networks are in danger with the settling
of particles with a high degree of energy which can over load the
network and create failure. At the sam etime such an erruption is a
reflection of the number of short life particles which are suitable
for particle ejection because they aproach the static level of energy
such that they can be ejected or levitated. All of this can be deduced
by the use of an arbtrary field as used by Gauss with the addition of
observations seen in his future to which he was not privy to. Maxwell
did not use the arbritary border system as he was a mathematician
combining number combinations for simplification. Fortunately all the
laws of others with which he played with included a vevtor required to
fill the gap in the vector arrangement so it would conform with
Newtons law
even tho they could not explain what the missing vector represented.
If other scientists did not include this vector which was absent in
their observations
then Maxwells laws would eventually prove to be useless.
And it goes on and on and
Goodnight

> Tomorrow honey dooo's

Yuno I am not fully convinced that Gauss did not provide the extension
to the law of Statics
as circumstances point to unsatisfactory performance by his assistant.
Gauss primarily a mathematician
interested in astomanry. visited a friend in Italy whose interest was
in magnetics so it was natural during his stay that Gauss would
cooperate
in the work even tho it was far from his choice of interest. It was at
that time that the law of statics evolved which is some distance from
magnetism
so I see no reason why he would not have added my extension.
Unfortunatelly his mathematical talents was not producing enough money
to live and it is
believed by some that this was due to his assistant not putting
Gauss's notes in order for publishing. Gauss was offered a job in a
Itallian observatory and his dabbling in magnetism and associated

areas came to a halt or abandoned. After Gaus died his former assistant appeared on the scientific scene with discoveries that many considered beyond his interlect which then produced rumors that finally faded away. So in away what I am relating is a detective story of the fraudulent happenings of yesteryear where the penalty of fraud was never enacted because of death. I know science blabber with no proof
but it would make for a good detective story or sci fi. Maybe I found those very notes and is now claiming them as solely mine and possibly a distant relative of the fraudulent nature. David now is your chance, redirect your energies so justice comes about

A go at what? That was your statement that I quoted.

>> 1. ï¿½If current flows along the inside of a wire, and not on the
>> outside, how does the field radiate through the alleged non-conducting
>> outer part of the wires? ï¿½The radiation would be trapped inside the
>> conductor, only to perhaps emerge at end

Due to the length of your extended sentences, I have to edit them in
sections to extract individual concepts.

>a length of radiator which is a fractional wavelenth will have
>charges in motion on the outside

I thought you said that fractional wavelength antennas have maximum
current on the inside of the conductor. (I'm lazy and don't want to
search for the specific quote). Please decide if it's inside or
outside.

>creating radiation
>the rest of the charge length will be inside the radiator where a
>magnetic field cannot be created and particles if they were present
>cannot pierce the eddy current on the surface.

Particles? Where do I get a bottle of RF?

Eddy currents only occur when there is an opposing magnetic field
restricting the flow of electrons. You might have such a problem in a
transformer design, but nobody designs match boxes, xformers, and
antennas that way:
<http://en.wikipedia.org/wiki/Eddy_current>

RF current flows on the outside of a conductor whether it's shorter or
longer than one wavelength long. Show me a formula where there's a
break point at 1 wavelength.

>For radiation at all
>times the radiator must be a wavelength or multiple thereof or a
>period of the frequency in use for radiation to not disappear from the
>surface where the levitating force is present to eject particles

Particles? Where do I get a bottle of RF?

My 80 meter antenna is considerably shorter than one wavelength. No
loading coils but a suitable match box. Are you telling me that my
antenna does not radiate?

>> 2. ï¿½If current flow along the inside of a wire, then it would seem
>> that increasing the effective diameter of the conductor would have no
>> effect on its impedance. ï¿½Measurements of the Q of large diameter
>> conductors versus small diameter conductors have show that impedance
>> goes down with an increase in wire diameter.

>the increase in diameter does not affect conditions that are
>exposed to air
>thus the progression of skin depth is the same.

My antennas are not affected by air. The dielectric constant of air
and a vacuum are sufficiently close to be considered identical. How
does the Q or impedance of an antenna change when exposed to air?

>Thus copper losses on
>the inside circuit
>will be reduced as well as lost radiation resistance in the circuit.

What inside circuit? Do you mean the inside of the conductor?
Radiation resistance is increased or decreased, not lost. It's not a
quantity that can be bottled or sold.

>I
>previously stated that
>copper losses on the inside of a fractional wavelength antenna must be
>considered separately from the groundplain resistance
>which is required i.e. they are two separate resistances in series.

Why must they be considered separately? My radiation resistance
calculations are the vector sum of the antenna impedance and any
resistive losses that present in the conductors. The radiation
resistance is not a resistance that can be added. It's an impedance
that has a phase angle that must be added as a vector.

>> 3. ï¿½How does a cage antenna work? ï¿½The effective diameter is huge, but
>> there's a giant hole in the middle, through which no current is
>> conducted. ï¿½If most of the RF current flowed through the center, and
>> there is no center, then a cage antenna can't work.
>
>I am not familiar with a cage antenna but from the above description
>is
> that it is transformed into a Farady cage

Nope.
<http://en.wikipedia.org/wiki/Cage_antenna>
<http://www.arrl.org/news/stories/2001/05/03/2/>
<http://forums.qrz.com/showthread.php?t=144503> (see drawing)
It's usually an HF dipole with insulating spreaders at each end. One
wire per spreader. This creates an effective wire diameter equal to
the spreader diameter without the necessity of using a huge piece of
tubing. The large effective conductor diameter increases the
operating bandwidth of the antenna. No effect on the gain or pattern.

No, I don't mean an elephant cage antenna:
<http://www.fas.org/irp/program/collect/an-flr-9.htm>
<http://maps.google.com/maps?q=http:%2F%2Fbbs.keyhole.com%2Fubb%2Fdownload.php%3FNumber%3D
112921&t=k&om=1&ie=UTF8&ll=61.26458,-149.847829&spn=0.00654,0.01914&z=16>
I want one...

>> I can conjur a few more rhetorical questions, but these should be
>> sufficient to illustrate the problem. ï¿½Your antenna current
>> distribution model does not fit very well with tested reality.

>Hmm why not?

Because I don't have infinite amounts of time to continue doing this.
I supplied 3 examples of common measurements and constructs that do
not fit into your model of current being maximum at the center of a
conductor. That will have to suffice for now, or at least until I
need some more entertainment.

>> Got any more prediction? ï¿½I need the target practice.

>Yes
>Earlier I pointed to the fact that eddy current can be neutralised
>such that particles canot be ejected from the surface

That's fine. Now, how do I measure those eddy currents? How are they
calculated? What affects their value. Where do I get a bottle of RF
particles?

>Indeependent testing showed there was nothing to prevent particles
>from settling on a diamagnetic substance thereby inducing
>an oscillation .

An antenna by itself cannot oscillate (except maybe in the wind). If
particles "settled" on the antenna, its weight would increase. How
much?

Are you familiar with the definition of diamagnetic?
<http://en.wikipedia.org/wiki/Diamagnetism>
Copper is non-magnetic. None of my antennas levitate themselves.
Diamagnetism will not create oscillations.

>At the same time on the transmitting side the
>particles were still present on the diamagnetic surface because the
>ejection force
>was neutralised thus preventing ejection otherwise seen as

>transmission.

Huh? What ejection force. If there were an ejecting or levitation
force on a copper antenna, it would be measurable. How?

>Another one
>The computor on the first example disapointed me as I expected a
>higher gain (stated on this net)

Here we agree. Measured gain always seems to be less than calculated
gain. That's due to the myriad of minor factors left out of the
calculations.

>When I corrected the nullification of
>the foucault current by separation the computor program gave the gain

Separation from what? Foucault current is exactly the same as eddy
current. Since your separate computer program generated numbers,
could I trouble you for the results? Incidentally, eddy currents are
always losses, not gains.

>I initiall expected in gun shot form which migrates in a way to a
>lazer ray which is oif a similar science
>thus HF does not necessarily have to diverge such that gain is
>nullified.

Brain overload. Cannot compute. Error....error....error... imminent
meltdown predicted.... abort... abort... pffffffzt!

>If you want more target to aim at listen for the BIG BANG and then aim
>at the resulting BLACK HOLE

Too late. My brain just collapsed into a black hole and will soon go
super nova.

Art, I am totally confused. I don't understand what you are
trying to say. Can you explain what you mean by the term
"Vector"? For something to be called a vector it must meet
a number of precise mathematical criteria. Note the
"Formal definition" at:
http://en.wikipedia.org/wiki/Vector_space

Actually, don't go out of your way. And, all you are required to do is be coherent and realistic ... and no, "empty" for the general population can go forward as it has/is/and-will-do ... the scientific community already knows "empty" has multiple definitions.

Frankly, I don't know how you can misinterpret even the most minor points of human decency ... to place words in anothers' mouth, without asking permission, is just considered rude and crude ... but then, that may just be indicative of ones background, schooling and place of residence ...

You saw that indication a few days ago. I said when
I used the word "empty" or "nothing" in the context
of quantum physics, I was talking about "absolute
nothing", i.e. absence of everything including space.
I have many references that supports that quantum physics
definition of "empty" and "nothing". If you take Webster's
definition literally, "empty" means "containing nothing",
including space, i.e. absolute nothingness.

There is a precedent for defining a common word within
a certain context. My physics book says: "In ordinary
conversation the word "power" is often synonymous with
"energy" or "force". In physics we use a much more precise
definition: *power* is the time rate at which work is done."

I am simply using a much more precise definition for "empty"
and "nothing".

yep, now it makes much more sense. art's management background now explains much of his behavior perfectly... this is the final necessary step, reassigning the underling to a worthless project to remove them from the productive project. It also explains the endless flow of technobabble, the grabbing on to recent events that have neat new buzzwords to add into his vocabulary, and the utter lack of understanding of basic principles. yes art, I'm glad you finally revealed the management background, it makes this all come into perfect focus. now we can all help you to continue your rise up the ladder to your maximum level of incompetence, or is that incontinence?? no, must be incompetence since everyone knows managers have a high bladder to brain ratio so can outlast everyone else at meetings... that must carry over to newsgroup posting also, you can sit at the keyboard and babble on longer than any of us that have a much lower bladder to brain ratio. come to think of it... gotta run... nice wx coming this weekend so I won't be around much, please go easy on the rest of the audience, they may not understand the management handicap as well.

Sorry, you are mistaken. Here's a quote of what Einstein said:
"The special theory of relativity does not compel us to deny
the aether. We may assume the existence of an ether, only we
must give up ascribing a definite state of motion to it, ..."

That's what modern quantum physicists have done. No
"state of motion" is ascribed to the particles winking
in and out of existence in the quantum soup of space.

Also quoting "The History of Modern Science":

"Einstein himself, in his application of relativity
principles to the gravitational theory (1915), supposed
that a gravitating body distorts nearby space, and that
these distortions determine the trajectory of a passing
ponderable body. An entity that can distort its shape,
deflect light, and propagate electric and magnetic
disturbances can be called a void only by discourtesy.
More recently, quantum electrodynamics has filled the
void with a vacuum that undergoes energy fluctuations
and acts as a theater for the creation and annihilation
of virtual particles."

If the void was absolutely empty, there would be nothing
there that could be distorted by gravity. Yet we know that
the void is indeed distorted by gravity. Ergo, the void
is NOT empty in the absolute sense of the word.

Please correct your incorrect concepts.

Continuing the quote from Einstein: "The special theory
of relativity forbids us to assume the ether to consist
of particles that can be tracked through time, but the
hypothesis of the ether in itself is not in conflict with
the special theory of relativity."

Continuing quotes from Einstein:
http://www.tu-harburg.de/rzt/rzt/it/Ether.html

"What is fundamentally new in the ether of the general theory
of relativity as opposed to the ether of Lorentz consists in
this, that the state of the former is at every place determined
by connections with the matter and the state of the ether in
neighbouring places, which are amenable to law in the form of
differential equations,; whereas the state of the Lorentzian
ether in the absence of electromagnetic fields is conditioned
by nothing outside itself, and is everywhere the same. The ether
of the general theory of relativity is transmuted conceptually
into the ether of Lorentz if we substitute constants for the
functions of space which describe the former, disregarding the
causes which condition its state. Thus we may also say, I think,
that the ether of the general theory of relativity is the outcome
of the Lorentzian ether, through relativation."

"Recapitulating, we may say that according to the general theory of
relativity space is endowed with physical qualities; in this sense,
therefore, there exists an ether. According to the general theory of
relativity space without ether is unthinkable; for in such space there
not only wonld be no propagation of light, but also no possibility of
existence for standards of space and time (measuring-rods and clocks),
nor therefore any space-time intervals in the physical sense."

So much for the ether being banished by Einstein. What is it about
Einstein's words, "the ether of the general theory of relativity",
that you do not understand?

Oh please, he claims not to understand ANY of it--everything he
reads/has-read/learned/etc. claims the opposite ... :-(

The only thing left? He then claims this has all been a "cleaver ploy!"
ROFLOL

Now, let me see, what ignoramuses have I seen using this "cleaver ploy"
in the past ...

A vetor diagram in my mind evolves around Newtons laws
All forces (vectors) forces when summed must equal zero.
Whether their is a triange or a polygon of forces it always leaves a
gap
whuch thus provides a vector required to make he arrangement equal
zero
and in a state of equilibrium. The masters always followed this
aproach to determine if equilibrium
was present by vectorizing all the forces known within a arbitrary
border. They always came up with
an unclosed vector arrangement even tho it met the requirements of
equilibrium. So all filled in the gap
o arrive at the starting point and labelled this unknown vector that
they were forced to provide as the weak force required for equilibrium
to satisfy Newtons law.

Draw either on a piece of graph paper. You will have your coordinates
that way when you mark up the grid.

Yep. That's what I get for trying to be helpful, an ever increasing
and more elaborate word salad of technobabble. My contributions
certainly didn't help. Now I know how Victor Frankenstein felt when
he intended to create life, and ended up instead creating a monster.

>This is all one very elaborate Troll.

Yeah, but I'm still jealous. I can't juggle technical terms as well
as Art has demonstrated.

It didn't take much effort to see how the smooth transition between
multiple topics was implemented. No sentence has a single subject or
action. By splicing two disconnected subjects or actions into a
single sentence, each sentence can seamlessly transition from one
topic to another. The next sentence picks up the 2nd subject from the
previous sentence, and then adds a 3rd subject, ad infinitum. That
has the benefit of it being very difficult to refute or even discuss
two subject simultaneously, without first surgically dissecting each
sentence into at least two parts. I attempted to do that in my
previous posting, with only marginal effectiveness.

I think I now have enough material to effectively study the technique.
It should be quite useful for writing business plans, patent
applications, and research reports. I would like to thank Art for the
material and apologize to the other readers for becoming part of the
problem.

I could go along with that. Let them use amateur power amps as well;
at least that would legalize their power amp hardware. Also, I think
CBers do have something to contribute in the construction of some of
those antennas those guys use; some are trash but others are fairly
imaginative at maximizing output power at that frequency. Also those
cheap Galaxy amps. Ise use one myself when I put 10m in my car.

No correction needed. This ether, i.e. the one which in your words
which the special theory of relativity forbids us to assume that it
consists of particles that can be tracked through time, is forbidden
by relativity. This is obviously the ether that was effectively
"banished" when Special Relativity came out in 1905 due to time
dilation effects when applying the Lorentz transformation. That was
not to say that another type of ether could not exist. I was very very
precise about that in my post. I know that Einstein later on did not
try to dispute that a different type of ether could exist. My point
was that Einstein himself did NOT hypothesize, postulate or theorize
that such an ether DID exist. Kostro seems to think Einstein did
theorize a new ether and that is wrong. That is where you and Jimminy
Cricket Smith are going off track. Suggest you re-read it.

I think you are confusing the "Weak force", resposible for "Beta decay"
in radio-active materials. The following web site explains the work
of Enrico Fermi in this area:
http://atomic-molecular-optical-physics.suite101.com/article.cfm/beta_decay_and_the_weak_force
While it is not unreasonable to consider Newtonian mechanics in
an explanation of what hapens within a conductor, there is no
missing force involved.

Computation of the electric and magnetic fields in the vicinity of a
conductor involve manipulation of the "Vector magnetic potential";
as in:
http://en.wikipedia.org/wiki/Magnetic_vector_potential

[loads of chit he hopes will sound authentic and intimidate others into either shutting up, or agreeing with him ... <puzzled-look>]

Actually, the "Luminiferous aether" was too narrow, by its' sheer definition; Einstein first denied it, then realized it must be replaced with the gravitational ether and that referencing motion in relation to gravitational ether has no meaning ... basically, if you give this any thought at all--this ether exists apart from time and motion, and any possible meaning of time we could attempt to ascribe to it. (time is motion, motion is time ...)

Indeed, this is just one property/aspect of this ether which is speculated on, the ability to jump from a point in it, to a far distant point in it, in "no time." A "folding of space" in some theories, a wormhole in others, etc. ...

You are an idiot, you cannot even get that right ... but, we considered the source, you are forgiven child. :-)

2756. Clarifying Space, "Ether" and Nothingness

Newsgroup: rec.radio.amateur.antenna
Date: 2008-09-20 00:58:25 UTC
From: dfinn1@nc.rr.com
Message-ID: <9f89fc96-29e0-426a-9e2f-6f82bfdb6367@i76g2000hsf.googlegroups.com>
Source record: 21829

Einstein did not prove or disprove or advocate an ether theory. He did dispel ether with any mechanical characteristics, which is what Cecil was talking about (at least he implied with his reference from an Einstein speec) and what I also have said before but hel did not recognize. From Cecil's earlier reference the following paragraph (from a speech long after 1905 by A. Einstein) is found:

"More careful reflection teaches us, however, that the special theory of relativity does not compel us to deny ether. We may assume the existence of an ether (but) only we must give up ascribing a definite state of motion to it, i.e. we must *by abstraction* (dfinn emphasis) take from it the last mechanical characteristic which Lorentz had still left it. We shall see later that this point of view, the conceivability of which shall at once endeavour to make more intelligible by a somewhat halting comparison, is justified by the results of the general theory of relativity."

A key word is "abstraction". That is what the philosopher Kostro does not understand. Johnny Smith, in plain English this whole exercise means that Einstein reflected that forces (in this case gravitational) can be considered to act on space, primarily. The force's effect on mass would then be a secondary condition that occurs due to the force's distortion of space. It is a rather cool way of looking at things...it is an acceptable way of conceptualizing the universe. Looking at space in such a way allows us to consider that "absolute empty" space must be "something" because forces act on it. Light follows space. Space directs the transport of light in a way that is fully dependent on the forces acting on space. The something can be referred to as a type of ether which directs the the transport of light. But this ether is an abstraction, depending upon whether you consider space or mass to be the "primary" entity upon which the forces act. Now Johnny, I really "get" the additional things that you are saying (they are things that have no relationship to this concept). You are calling your ether something that is material, which Einstein definitely ruled out in the Special Theory in 1905. You drag out the well-known hypothesess about the exotic matter stuff, with particles popping in and out of physical form in space-time and neutinos or whatever and call the physical matter (or perhaps exotic matter) "the ether". Even though Einstein ruled that out material ether in 1905, let us bring back the material ether once again for nostalgic purposes. We then find that these exotic/physical matter alternations do not occupy all of space all of the time. This means some parts of space truly are absolutely "empty" some of the time. What is there to propagate your light waves at those points in space-time when the material ether is not there and the space is absolutely

empty? hmmmm...and to add insult to injury, Cecil is faced with the prospect that at some coordinates in space, some of the time, there exists "nothing" some of the time. I agree with Einstein's *abstract* ether in exactly the same way that Einstein does: only when you consider space the primary. But no one says I must take space as the primary; to me it is still more obvious that matter should be the primary, where no ether is required or indicated.

2768. Final Word on Relativistic Ether

Newsgroup: rec.radio.amateur.antenna
Date: 2008-09-20 05:54:45 UTC
From: dfinn1@nc.rr.com
Message-ID: <f509e5bc-4feb-4959-878b-6725baaa46d6@d45g2000hsc.googlegroups.com>
Source record: 21841

This Google web interface places limits on my posting so I guess I will have to put in my last word on this, assuming I can still get this posted. "John" may be rsponsible for my posting problems. My response is as follows:

Cecil is referring to the (abstract) ether of the general theory...Please understand that Einstein was saying that space itself is an "ether" IF you consider space to be the primary force acted upon by gravitation because space then "controls" phenomemon of light propagation. Space is "manipulating" the light path in accordance with gravitational forces present; it acts like a medium, like an "ether". It is like Cecil and "John" are reading a parable in the Bible and they are reading the story literally without looking for the essence of the story. He was not speaking about an ether as a physical entity that really exists in material form in a motionless, non-relativistic setting that most of us find ourselves in (we are not photons). It is an abstraction for us. Do abstractions exist? Yes. As physical entities? No. Can you physically measure an infinitely large number of infinitely small rectangle under a curve? No. Can you compute the area under the curve by use of calculus which uses that principle? Yes. The Einsteinian ether you are referring to is as much an abstraction in our non-relativistic existence as the Newtonian infinitely small rectangles of a calculus integral, i.e. an abstraction.

here is the best description of art's equilibrium i have found:

Perturbative string theory may be used to show that massless particles can
only have spins 0, 1/2, 1, 3/2, 2. This conclusion follows from an analysis
of the energy of various harmonic oscillators included in the string that
contribute to the mass of the resulting particle. This conclusion
beautifully agrees with facts about gauge invariance that may be derived
using spacetime arguments.

If you consider any semirealistic physical system, it reduces to quantum
fields at long distances - fields that are able to create particles. Because
of the rotational symmetry, these particles may be classified according to
their spin. For spins equal to 0 or 1/2, one only creates states of positive
norms (think about the Klein-Gordon and Dirac fields). However, for spin 1
and higher, there are inevitably negative-norm states in the Hilbert space
created by the simplest version of these quantum fields. For example, the
time-like component of a 4-vector field creates states whose norm has the
opposite (negative) sign than the space-like components of the same field.
Such a decoupling implies an infinite amount of accidents that are
equivalent to a symmetry.

Elevator motors are DC, in the old one the DC was supplied by a motor/
generator combination, The new ones get their DC from a huge SMPS and
they can be electrically noisy. They can also induce harmonics into
the electrical system that UPSs dont like at all. It is my
understanding the elevator rehab project where I work has been put on
hold for that reason.

Quantum Physics tells us that particles are the only
things that exist in reality so since space exists,
it must be made of particles without which space couldn't
exist. My personal opinion is that Quantum Physics is
correct and that's what I was paraphrasing above.

My personal opinion is that Einstein was correct when
he said:

"Recapitulating, we may say that according to the
general theory of relativity space is endowed with
physical qualities; in this sense, therefore, there
exists an ether. According to the general theory of
relativity space without ether is unthinkable; for
in such space there not only would be no propagation
of light, but also no possibility of existence for
standards of space and time (measuring-rods and
clocks), nor therefore any space-time intervals in
the physical sense."

Replace "physical qualities" with "particles" in
accordance with the latest thinking in Quantum
Physics and you will have arrived at my personal
opinion. Feel free to continue to harass me for
having opinions based on science. In exactly what
ways do you disagree with Quantum Physics and
Einstein?

The FCC "First Class Radio Telephone Operator" license was replaced many years ago by the "General Radiotelephone Operator License."

The General license was issued automatically to anyone sending in a First 'Phone license for renewal at the end of its term, and is valid for the lifetime of the licensee.

Here is an FCC link about the General...

What equipment do you build for the amateur bands? Where does one
employ that much theoretical physics?

I have software and analyzers to help me; I don't need to throw
general theory around on a bulletin board that is over the head of 95%
of the people whose curiosity might be piqued by the name of the group.
Perhaps if you applied your quantoid lunacy to making a suitcase
quadrifilar helix for HF or something, I'd be less hurt.

> of relativity does not compel us to deny ether."

Could be, but what about the general theory of relativity
which came later? You seem to be missing the fact that Einstein's
statement applies to the *special theory of relativity* which
preceded the *general theory of relativity* about which Einstein
said in 1920:

"Recapitulating, we may say that according to the general
theory of relativity, space is endowed with *physical qualities*;
in this sense, therefore, *there exists an ether*. According to
the general theory of relativity, *space without ether is unthinkable*;
for in such space there not only would be *no propagation of light*,
but also no possibility of existence for standards of space and time
(measuring-rods and clocks), nor therefore any space-time intervals
in the physical sense."

According to Einstein, the ether is a necessary requirement
for the general theory of relativity to be valid. Without ether,
there would obviously be no propagation of RF either. As I said
earlier, EM waves cannot propagate through absolute nothing and
I am just agreeing with Einstein.

> Einstein reflected that forces (in this case gravitational)
> can be considered to act on space, primarily. The force's effect on
> mass would then be a secondary condition that occurs due to the
> force's distortion of space.

You have a built-in contradiction there. If gravity can distort
space, then space consists of particles upon which gravity can
act (in accordance with the tenets of quantum physics). They may
be exotic particles but particles nonetheless.

> You are calling your ether something that is material, which
> Einstein definitely ruled out in the Special Theory in 1905.

But by 1920, Einstein had reintroduced a physical either as
a necessary condition for the general theory of relativity

to be valid.

Quantum Physics tells us that everything that exists exists
as particles. If that is true, then everything that exists
is indeed "material" although ether is most likely an "exotic
material" like (or maybe the same as) dark-matter/dark-energy.

Einstein said: "... we may say that according to the general
theory of relativity space is endowed with physical qualities ...
According to the general theory of relativity, space without
ether is unthinkable."

I don't recall Einstein saying that his ether was just an
abstraction devoid of physical qualities. In fact, he said
space is indeed endowed with physical qualities. And that
was long before dark-matter/dark-energy theory had been
introduced.

Quantum Physics tells us that everything that exists exists
as particles.

We have not discovered all of the particles. We may not even
have conceived of all the particles. We have accounted for
approximately 5% of the material that exists in the universe.
It doesn't take a genius to postulate that some of the missing
material may be in the structure that keeps space from collapsing
into absolute nothingness.

I had one about the same time. They do expire every 5 years. There is no longer a First or Second class license. They were converted over to a nonexpiring General license. That thing is almost useless now. Most of the old requirements to work on transmitters have been eliminated.
As your First class has expired, you will have to take the test again if you want the General.

Cecil:

I am just telling you what I see suggested in his papers, lectures and talks (not to mention a whole slew of others chiming in along the way) ... and, of course, even Einstein himself found it, almost, unbelievable! Indeed, he made a direct comment to this (not before me right now, will quote it later.)

But, yes, although "the how we will do this" is much like space/structure/ether--at this point, it requires a wee-bit of faith ...

Cecil:

When ever I become timid, cautious and have a lack of courage in being able to state exactly where it appears "we are being taken", or what is possible, I think what existed before my birth and early childhood: (indeed, I am still such a coward on these matters, I tend to stick to what Einstein suggests!)

1) We didn't have the Maser/Laser. (Buck Rogers ray gun)

2) We hadn't been to space nor walked the Moon. (only speculated on it in science fiction)

3) Our doctors still appeared like Witch Doctors (well, they still do, a bit, baby steps, baby steps ...)

4) Computers were mere "toys." (a decent one would have occupied square miles and consumed the output power of nuclear reactor)

5) The speed of sound was considered a "wall", much like the speed of light today ...

6) [Continue this almost endless list--at will ...]

Back then, mention any of these advances as speculations on where the science "of the time" was about to go, you would have been laughed out of the room--why should we expect different today? People/society just doesn't change "that much", that quickly ...

Regards,
JS

I have worked on maybe 5 CBs, a little Marine and did a Avionics project. Most of my time was spent with cutting edge PLMR and SMR projects for commercial, business, and Industrial customers. Most of those customers have gone to the phone companies though.

I was successful with the Fire customers, but the LE bunch always wanted a piece of the action. Hard to subsidize them when they are THE only action left.

They may have automatically converted you. I too let it slide but they converted and renewed it to lifetime anyway. You can look up your name (the one that you used) in ULS and find out if you have an active license. They seem to like to keep their database entries. I couldn't even throw mine away.

Here's the search page to look yours up:

I'm serious. It's kinda like the red light districts in many cities.
If you can't supress prostitution, at least you can control it in a
confined space. Give the lunatics room to jam each other, and they
won't be tempted to land on licensed frequencies.

It's also great for contesting. The art of rudeness, jamming, and
tuning up on other peoples conversations have been sufficiently
optimized on the ham bands. Time for a new challenge, which will be
contesting in a band full of hostile interference. I was running
PSK31 on CB for a while, much to the irritation of the channel
"owners". Worked nicely and there was little intererence. I consider
this advancing the state of the art in communications effectiveness.

Surely the FCC and Congress will recognize the value of ham radio to
global harmony, where international cooperation is enhanced by the
wireless exchange of a signal report, call letter, and contact number,
with foreign operators sufficiently politically connected to obtain a
ham radio license in their country. Perhaps ham radio should be
nominated for the Nobel peace price.

I dread to think what such hams might do with their spare time if ham
radio were to disappear. Give them a sandbox in which to play and get
out of the way.

>Like this?
>http://members.cruzio.com/~jeffl/pics/antennas/index.html

Ugh. That's my "old" site, where I've been playing with JAlbum
formatting. I haven't updated it in a while. Go unto:
<http://802.11junk.com/jeffl/antennas/>
for the latest version. The coffee can antenna is in there with
better 4NEC2 output.

Ooops. The NEC model files seem to have evaporated. I'll fix later
tonite.

>What equipment do you build for the amateur bands? Where does one
>employ that much theoretical physics?

I spent about 15 year repairing commercial 2way radios, designing
accessories, working for several radio manufacturers, and playing RF
consultant. Methinks I can count about 15 independent products I
helped design during this time. None of them were specific to ham
radio, but could be adapted for ham use. At no time did I ever resort
to theoretical fizzix, quantum theory, or other occult arts. However,
I did employ a few magical incantations, especially when things did
not work as expected.

I never even suggested that theoretical fizzix was involved in the
design of amateur radio and antennas. Please re-read what you quoted
from my previous posting. Do you see any fizzix in there? What are
you suggesting?

Incidentally, since quantum theory violates every rule of logic,
causality, rationality, common sense, conventional wisdom, and
intuition, I've always suspected that it was a refuge of such
thinkers.

> I have software and analyzers to help me;

Same here. However, my analyst charges far too much money per hour
and is used sparingly.

>I don't need to throw

>of the people whose curiosity might be piqued by the name of the group.

Then don't throw general theory around. Nobody will learn anything
new. Ham radio will remain exactly as it is now and has been since
the invention of radio. Progress will cease and life will be easy for
all involved.

>Perhaps if you applied your quantoid lunacy to making a suitcase

> "According to the general theory of relativity,
> space without ether is unthinkable." Albert Einstein

In most of science, God is unthinkable. But then, God said he won't do tricks for non-believers. "The fool in his heart says there is no God"

I can't conceive of God being a medium, but perhaps he is all that and much more. There is no "nothingness" Philosophically. Only degrees of scarcity of something that we perceive or expect to be there. Space is predominantly empty of matter but there is some from time to time. Perhaps the stars, planets and other phenomenon are there to keep the space clean. We don't fully know what we don't perceive (damn little enough what we DO perceive) . "Ether" is a supposed medium that facilitates an operational paradigm.

Bottom line is: Not all things must be theoretically proven to be practically utilized. The fact that a theory is practically utilized in a given application, does not infer that theory is infallible. For instance, in the application that at any given instant we are oriented with respect to the tangent of the Earth's surface. So that for the case that we are instantaneously at one point on the Earth, it doesn't matter if the Earth is flat, round, oblong or Spherical, even though it has been proven otherwise. Likewise, to think that an experiment that uses a particular theory and is successful will fully prove that theory over another yet to come is foolish.

So, conclusions based on application of far reaching theories should be held at arms length that we might maintain our objectivity. After all, Einstein and Newton both died before they could achieve a unified theory of the universe. Nor do I expect those still living will either. For now, none of them have been proved infallible.

"FREE SPACE" with respect to antenna theory is what? I thought it was conceptual place so an antenna with a known potential at it's terminals could be evaluated without ground effects. Is there truly a difference for our calculations between outer space and several wavelengths above ground in reasonably dry air?

Hello John,

As others say, it depends on the frequency, actual application and
ferrite type.

M o s t snap-on ferrites use "fast" ferrite material, so they are
effective (read: give highest impedance) at several hundred MHz.
When using at low HF, the effect is limited.

I checked the 2008/2009 WURTH catalog (it is on my table): You can
expect common mode impedance (one turn, inner diameter suited for
8..12mm cable) of about 50…120 Ohms at 10 MHz. At 3.7 MHz impedance
drops to about 25 to 45 Ohms. Putting more of them onto the cable
gives proportionally more impedance.

It depends on the common mode impedance at the intended position
whether they will be effective. As OCF dipoles have high common mode
impedance, you have to use many of them (weight increase?).

When you think you need them at low HF, you might add some ferrite
rings/sleeves with high relative permeability (you probably have more
choice in ferrite materials in ring/sleev shape). The rings do act at
the low HF part, while the clamp on ferrites act on the high HF part.

> 73, Cecil http://www.w5dxp.com

Good Grief indeed. You are reduced to playing word games. The physical operant of gravitational force from an entity of mass is another entity of mass or one with the some of the physical qualities of mass such as light. Since the gravitational force between 2 or more entities may affect the space between such entities, we can form the abstraction which considers that gravitational force distorts space as the primary operant of this force and its effects on mass and light are secondary results of the distortion of space. In your posts you have surprisingly chosen to view space as the latter (abstract view) giving almost no consideration to the physical view where matter-to-matter is the primary operant. I prefer the physical view because I reference my thinking as an oberserver at rest. A big problem with chosing the abstract view (matter-space operant) is that it depends upon no future findings ever being discovered that would alter the theory upon which it is based, But I agree, IF the General Relativity theory is ever proven to be an endpoint upon which no additional finding can ever be found, and you know this will never be the case, then according to the 1920's abstract view, space itself must be *the* ether for light (as least, as far as the "light" is concerned). This non-material ether "with Physical qualities" as Einstein calls it, can never be observed or measured because it is an abstraction to us at rest. Your view can never be proven false until such time as the general theory is modified which will not happen in our life time. This puts you on safe ground in that you cannot lose the argument. Neither can you win. I can see that you are about 75% there in "getting" relativity...you can't get there with word games. I suggest you confine your concepts of the physical world to 4 dimensions where you, the observer are at rest. Everything you see in that setting is your "physical" word". From there you can conceptualize the universe as if your were an observer at relativistic speeds. Everything in that world is an abstraction. Then consider that physical elements and

abstract elements of an observation can be true at the same time even if they seem to contradict each other in one or the other setting. But never mix up the two universes as you are doing right now. Finis.

2804. Eico GDO coils

Would anybody who owns Eico model 710 GDO be willing to supply coil data (diameter, length, No. of turns, wire diameter) so that I could duplicate the coils? I bought the coil-less 710 at the fleamarket and cannot find the coil set. I am mainly interested in the 2.9-7,5 and 7.5-18 MHz ranges. Or maybe a close-up photo with a ruler laying next to the coils would be enough.

The coils are bound to have so many turns that they will be hard to
count, unless someone actually unwound them.

Open it up, see if you can figure the capacitance of the variable
capacitor (or maybe there's a schematic somewhere that provides
that information?), and then use the equations to figure out the
needed inductance and then the number of turns to make that value
of inductance. Then you can use any size coil form, just so long
as you can rig it to fit whatever the GDO is using for the coils
to plug into. Wind some extra turns, and then remove them if
necessary (since it's easier to remove than add turns).

It won't be exact, but any GDO dial is fairly vague. The inherent
capacitance of the coil will come into play, so you can decide whether
it's best to have the GDO dial match at the high end or the low end.

Thirty years ago there was an article in "73" about revamping a GDO,
I think he solid-stated it but can't remember, but he didn't have a
coil set either and described the process he went through to give
it a set of coils. I think it was radical surgery though, I seem
to recall that he even changed the jacks used for the coils. He
took the easy way out, providing a jack to feed a frequency counter
so the original dial was relatively unimportant.

Michael Black wrote:

> ...
> Michael VE2BVW

So then, start out with the highest frequency coil--this one you should be able to count the turns on.

Then, look at then next, wind it, test it, and adjust turns so that in conforms to the expected frequency coverage of the "next band."

Then, sit down with your calculator and "predict" the next ... adjust your calculations and predict/compute the next ... etc.--repeat as necessary ...

Logic ... it pays off in the long run, is usable across all disciplines ...

Yech, tubes. I have several Heathkit grid dip meters, but no Eico.

This may help:
<http://www.qsl.net/n4xy/GDO_EICO.html>
The photo shows one coil, which should give you an idea as to the
general size and construction of the coil.

The photo of the Eico 710-A looks very much like one of my Heathkits
(buried somewhere). Do you have a 710 or a 710-A. There's a huge
difference.

>I bought the coil-less 710 at the fleamarket and

Others have suggested cut-n-try which is probably good enough. As
long as the coil looks roughly like the original, it should work.

However, if you wanna do the math, look at the schematic and figure
out the minimum and maximum capacitance on the variable tuning
capacitor. Be sure to include any trimmers or padding capacitors in
the tuned circuit. You know the lowest and highest frequencies from
the dial. Drag out your abacus and plug the numbers into the usual LC
resonant frequency equation. Solve for a value of L that will be
roughly the same at both the high and low ends of the dial. You
probably won't hit the exact value, but it should be close. Lots of
online calculators for the inductance of solenoid wound coils. No
need for an LRC meter as you can just plug it into the grid dip meter
and count the frequency.

Oh-oh. My Heathkit coils do not have ferrite or iron slugs. The Eico
710 coils apparently do. The coil on the left is obviously broken.

Free manual for the Eico 710:
<http://bama.edebris.com/manuals/eico/710/>
I'm too lazy to find a DejaVu decompressor, but I expect there are
some instructions and diagrams of the coils in the manual.

Yep. 4NEC2 will open .EZ files from EZNEC directly. I'm not very
familiar with MMANA-GAL but it appears that Ari's utility will both
import and export .NEC files.

Any tutorial from any vendor is useful. There's no reason to just use
one modeling program. If you had a workshop, would you use one tool
for every job? Probably not. If you sign in to the free Antennex
"guest room", there's a rather long and detailed NEC2 manual, along
with lots of tutorials and articles from back issues.

However, despite the wealth of tutorials and articles, I find it best
to learn by destroying. I hate to recommend my method because it's
not for everyone, but I like to start with a similar model, and
butcher it so I know how it works and what it does. If I can't figure
out how to do something, I search and read the docs. Not the best
method, but works for me.

I use mostly 4NEC2 because I'm familiar with it and because it
includes a surface, dish, cylinder, etc generator. I sometimes use
the free version of EZNEC, because it's somewhat easier to use. I
also use NEC-Win Synth to build tower and geometric structures:
<http://www.nittany-scientific.com/nws/index.htm>

There are lots of antennas available at various sites to plagerize.
For example:
<http://www.nittany-scientific.com/examples.htm>
<http://www.cebik.com>
<http://www.antennex.com>

Drivel:
Various commercial digital TV antennas:
<http://www.hdtvprimer.com/ANTENNAS/comparing.html>
with Eznec NEC2 files at:
<http://hometown.aol.com/kq6qv/SIMS/>
I'm amazed at how well some of these antennas work over the very wide
TV VHF/UHF range. In the past, I've assumed that much of the metal

work on the typical TV antenna were decorations and that the antenna was at best a marginal proposition. Apparently not, as most of the commercial antennas seem to be rather well designed.

Thanks. ULS, CORES, FRN numbers, and such started around 1998(?). It
was essentially optional (because the system didn't work) until about
mid 2000, when Congress demanded that all business with government
agencies include an SSI number (social security number). To get an
FRN number, you need to supply an SSI number.

I passed my GROL in Nov 1994, somewhat before FRN numbers were first
issued. Prior to that, I had an FCC 2nd and later 1st RadioTelephone
license with radar endorsement. I didn't want to deal with the ULS
mess so I avoided getting one. I eventually wanted to upgrade from
Technican class to General class[1], and which required an FRN number.
Oh well. Some of my friends and accomplises that obtained GROL
licenses at the same time as me still have not obtained FRN numbers.

[1] I was going to just sign the paperwork for the General class
license as I had passed 5 wpm back in the stone age of ham radio as a
Novice. However, the VE assured me that the price was the same for
the Extra Class license, so I should try taking it anyway. The logic
seemed reasonable except for one problem. I hadn't studied for the
Extra in the slightest. So, I blundered, guessed, snarled, and
muddled my way through the Extra exam, fully expecting to fail
miserably. I had to borrow a calculator. I was amazed when I passed
the Extra by one question. I'm fairly sure I answered all the
technical questions correctly, but missed most of the operating, band
limits, sub-bands, rules, and regs.

Yeah, working as a software engineer and finding I get the most money from convincing those "with money" that I am worth "some of their money" has made me aware of the value of reverse engineering--whether software or hardware--it works!

But, if you have built enough "old box tube xmitters", you can almost guess the dia./turns/and-caps <wink> Heck, bet I could come up with a circuit using the same coils, using a fet, and saving the cost of the filament power! Indeed, if the tube uses an octal socket, in his current GDO, why not replace the tube with a fet(s)?

The very first think I did when starting a new product, was to do a
"survey" of the competitions products. If possible, some were
purchased, dissected, reverse engineered, and on one occasion, cloned.
No need to reinvent the wheel when the competition has done it for
you.

>But, if you have built enough "old box tube xmitters", you can almost

Because the typical FET as a much higher transconductance (typically
about 30 millisiemens versus 5 millisiemens) and a much wider
frequency response, that you'll probably spend considerable time
stabilizing the oscillator. It's not easy to build a tunable
oscillator that operates over such a wide frequency range. Also, the
grid and gate currents are quite different. It can be done because
there are FET grid dip oscillators available. However, if you compare
schematics, they are sufficiently different to require a rebuild.

It's also criminal sacrilege to despoil such a vintage boat anchor.

The present time on a amateur license is 10 years, with a 2 year period for renewal after that.

To query a license the URL is: http://www.arrl.org/fcc/fcclook.php3

There are also other avenues to go from that URL .

Lots of luck, Rollie

> "According to the general theory of relativity,
> space without ether is unthinkable." Albert Einstein

In most of science, God is unthinkable. But then, God said he won't do tricks for non-believers. "The fool in his heart says there is no God"

I can't conceive of God being a medium, but perhaps he is all that and much more. There is no "nothingness" Philosophically. Only degrees of scarcity of something that we perceive or expect to be there. Space is predominantly empty of matter but there is some from time to time. Perhaps the stars, planets and other phenomenon are there to keep the space clean. We don't fully know what we don't perceive (damn little enough what we DO perceive) . "Ether" is a supposed medium that facilitates an operational paradigm.

Bottom line is: Not all things must be theoretically proven to be practically utilized. The fact that a theory is practically utilized in a given application, does not infer that theory is infallible. For instance, in the application that at any given instant we are oriented with respect to the tangent of the Earth's surface. So that for the case that we are instantaneously at one point on the Earth, it doesn't matter if the Earth is flat, round, oblong or Spherical, even though it has been proven otherwise. Likewise, to think that an experiment that uses a particular theory and is successful will fully prove that theory over another yet to come is foolish.

So, conclusions based on application of far reaching theories should be held at arms length that we might maintain our objectivity. After all, Einstein and Newton both died before they could achieve a unified theory of the universe. Nor do I expect those still living will either. For now, none of them have been proved infallible.

"FREE SPACE" with respect to antenna theory is what? I thought it was conceptual place so an antenna with a known potential at it's terminals could be evaluated without ground effects. Is there truly a difference for our calculations between outer space and several wavelengths above ground in reasonably dry air?

Two thoughts, both wrong. It takes very little investigation to
confirm their errors.

The greatest proponent of science, accuracy, and religion (thus
confounding the first quote above), Lord Kelvin, offered:
"Do not be afraid of being free thinkers.
If you think strongly enough you will be
forced by science to the belief in God,
which is the foundation of all religion.
You will find science not antagonistic
but helpful to religion."
quoted by
Rev. Professor Henslow, May 1903

Similar quotes from Einstein, Oppenheimer, Feynman... are legion.

>Is there truly a difference for
>our calculations between outer space and several wavelengths above ground in
>reasonably dry air?

This appears to be set up with the word "truth" to always yield a
proof of invalidity. Any standard reference reveals the difference
and is so commonly available as to make one wonder how this question
arrived on the doorstep. Engineering deals not with truths (however
many would like to force fit that term into conversation) but with
practical implementations. Is there a practical difference for our
calculations? No, not unless you have a particular need for accuracy
and precision. Precision is often unnecessary, especially extra
digits stretching beyond the resolution of the original data supplied
to give those computational results. However, accuracy is all, but it
does not demand the nebulous qualifier (in itself a distraction) of
"truth."

You can be accurate to 1 place of resolution, or to 10. Men have been
sent to the gallows without any precision or accuracy of a measurement
and that verdict was weighed on the "truth" of the evidence. Men have
been rescued from the gallows on the basis of parts-per-million
discrepancies that proved their innocence, and "truth" was never
determined, only falsity.

Of course there's at least one god. How else would you explain why my designs work? Science, logic, modeling software, and common sense all suggest that my antennas will never work, yet they do. I credit their success to divine guidance and inspiration and refuse to entertain any other explanations.

For those that believe, you're preaching to the choir.
For those that don't believe, you're wasting your time.
For those that aren't sure, a good sales pitch might work.

>"FREE SPACE" with respect to antenna theory is what?

It's a hypothetical condition, where an uncharacteristic fit of generosity causes the site owner to not charge for antenna space on his tower. I don't think that's happened since biblical times, but miracles are always possible.

Around here, if someone mentions ether, they're probably running a Methylamphetamine lab.

Richard:

Well written!

Yes, if one journeys in quest of an equation, a formula, a design parameter, a workable solution--all are within in grasp.

If ones journeys to find "the truth", one finds himself/herself on the path of infinity ...

I took the General Radiotelephone Operator's License exam in 1981, just
after it went into effect. However, they were still giving the old 2nd class

exam, which was mostly about tube technology and which shared nothing in common with the Extra Class amateur exam of the time.

My original license number was PG-3-110. I took the exam for the radar endorsement a few months later and they changed the license number to something else, which slips my mind at the moment.

Hi Tom,

I think I will amend this statement to no particular affront to you. I would say Physicists as a whole love God, they are secure enough not to have to "prove it," and they find some unfortunate religious zealotry as a curious mix of superstition, bigotry, and vanity. Every scientist who marvels at his or her own limitations in the face of discovery is in awe of creation. Everyone who wants to pigeon hole creation into categories of truth, righteousness, and a means to define morality have been swinging hammers on the crucifix for 2000 years.

They argue with a perverse ferocity like they can't sink that nail deep enough.

I will return to my email with several who prefer to discuss antenna design.

Jeff, thanks very much for your suggestions and links. I have actually already downloaded BAMA manual (Dejavu plugin works great on IrfanView 4.20, saves as pdf) and I will get to work calculating the approximate inductances. The variable C is the only component they don't show the value for, but I'll take a guess, wind a coil and listen for the signal. Then with some trial and error I can probably come up with a couple of coils for the ranges I am interested in. I know the scale won't be accurate, but in this day of digital readouts it's not important.

I am fascinated with the number of GDO's shown on N4XY's site - I remember seeing just Heath, Eico and an old Mullen.

Thanks agn

I think I have a pretty good idea from various pictures of Eico or
other GDO's what the coils should look like. I want mainly to get the
instrument operational on 80-20m ranges, so there won't be too many
turns. I have the manual but there is no variable cap value - looking
at it and comparing to standard BC band 365pF it can't be more than
50-80 pF per section. So as you say - calculate the inductance, wind a
coil... etc. adjust the winding until I hit the dial on one end.
Sounds like a lot of work for the old clunker, but I have the time and
enjoy this kind of stuff...

I have no problem with acknowledging the existence of God, though I doubt that God often takes the form of George Burns.

On the other hand, it is religion that I detest - as though God would speak with only one man and then depend upon that man to spread His Word accurately throughout Creation. (there - now I can remove my aluminum foil helmet...)

Ed:

You sound like myself. However, I was raised catholic and was too ugly for any priest to want to molest; I was always checking out the nuns anyway, so you can imagine how desperate I was! But then, that is all a story for another day ... <chuckle>

However, like so many, I jumped on evolution as soon as I found out "it was the intellectual thing to do." However, you know where that road goes--pursued long enough, it is a large circle which leaves you with the possibility of a supreme being or race (Gods and Angels? ... well, what can I say, they'd look like "Gods" to us!) Indeed, evolution makes one take a larger "leap of faith" than alternatives--indeed, IMHO it is just another "religion" to replace another ... but then, that is all a story for another day, also ...

My burning questions:

1) Did God build an ether to be exploited? (and it sure does look like it!)

2) And, if so, what type of antenna to do this would be required? (and, firstly, is there any phenomenon occurring which would indicate an area to explore in pursuit of this/these end(s)?)

Regards,
JS

That will work as long as you don't accidentally land on a
sub-harmonic. Methinks a frequency counter might be more useful than
tuning around the bands looking for the signal.

If you have a capitance meter or bridge, it might be possible to
measure the value of the tuning capacitor.

>Then with some trial and error I can probably come up with a
>couple of coils for the ranges I am interested in. I know the scale
>won't be accurate, but in this day of digital readouts it's not

Chuckle. A few months ago, I won a used HP something universal
counter on eBay because I wanted the extra digits of resolution.
However, that was for period and event counting, not frequency.

>I am fascinated with the number of GDO's shown on N4XY's site - I
>remember seeing just Heath, Eico and an old Mullen.

Search Google for "base dip oscillator" and "gate dip oscillator".
There are a few designers that couldn't find the grid pin on the
semiconductor devices. My Heathkit HD-1250 calls it a "solid-state

dip meter".

I don't know if this will help, but the HD-1250 looks very much like the Eico (other than the tube versus the xistor). Here's a table of coil values for it assembled from various parts of the manual:

MHZ uH
L1 1.6 - 3.4 171 red
L2 3.2 - 6.6 41.1 orn
L3 6.3 - 13 10.2 yel
L4 12.5 - 26 2.62 grn
L5 25 - 51 0.72 blu
L6 48 - 100 0.196 vio
L7 100 - 250 ???? brn

As usual, no value on the tuning capacitor in the manual, but it can be calculated from the above data.

Isotropic antenna. Works equally lousy in all directions for hearing
the big bang background hiss (the voice of creation). It's also
non-denominational, non-polarized, and non-existent. It can't be
seen, found, built, or purchased. Think of it as a miraculous antenna
that only the gods can appreciate and use.

As usual, man has attempted to mimic the gods by attempting to build
an isotropic radiator. It's close, but no miracle antenna.
<http://802.11junk.com/jeffl/antennas/isotropic/index.html>
Argh. The .NEC files have disappeared again. I'll fix (after I'm
done rebuilding an air compressor).

I did 2nd Phone in the late 70's and there was tube, transistor, RTL and TTL logic theory, and 'complete the schematic' type questions but less of that and more general types of engineering and circuit theory, AC/DC theory, RF and transmission lines and most of it involving Electronic Math. Trig, Vectors, no Smith charts or Calculus. Very little of it had anything to do with tubes specifically. The rest was FCC parts. It was said at the time, that it was more like the Advanced Ham ticket. I got my Advanced a year or two before, and I agree the technology level was equivalent and it was about 200 questions or so. Later when I did the Extra, (90's) there were questions well beyond the 2nd Phone but only 25 of them! The code test and the noise floor equations made me strain. I wish the bandwidth and modulation questions were on the Technician class test though.

Jimmie wrote:
"Is there a website that may have this data?"

I got my first class phone ticket in 1949. My house was destroyed recently my tickets and degrees went with it.

Commercial tickets have been converted to non-expiring "General Radiotelephone Operator Licenses". The FCC maintains a list of the commercial licenses it has issued.

When I wrote the FCC requesting a replacement certificate, they responded saying my request had been "dismissed". Then I wrote to The W5YI Group which advertises in QST. They said to send them $20 and within a few days my replacement "General License" arrived from the FCC in the mail. I highly recommend their service! Their address is:
W5YI Group
P.O. Box 565101 Dallas, TX 75356

I had been issued First Class Radiotelephone License No. P1-9-12391 in April 1949.

W5YI Group also got me a new copy of my KB5WZI Amateur License which had also been destroyed. I believe their fee for that was $7.5o. All this is very reasonable considering the hassle of trying to deal directly with the FCC.

Fortunately, my university says it encourages the display of degrees and will glady replace them at no charge.

Best regards, Richard Harrison, KB5WZI

Which brings me to another one of my boat anchors - GR-1192B freq.
counter which worked fine for 20 years just stopped counting. I am
trying to find a manual on the Manual exchange group but so far no
reply. No BAMA record, either. I know the new counters are cheap and
tenth in size, but the neon display tubes look so nice...

Just got mail from K7ITM offering to supply the Eico coil info. Thanks
for the Heath data.

Cecil, W5DXP wrote:
"But by 1920, Einstein had reintroduced a physical ether as a necessary condition for the general theory of relativity to be valid."

Recall the high school physics experiment of a clock ticking inside a bell jar. The air is then pumped out. When the air is nearly all gone, the clock ticks become nearly inaudible but you can still clearly see the clock. If ether had been inside the jar it would have been evacuated too and the EM lightwave would have lacked a medium, making sight of the clock disappear along with its sound. It seems likely to me that this experiment indicates that no medium is required for transmission of light despite the need of a medium to transport sound.

Richard;

You can also go on line to the FCC website and obtain a copy of your
license for nothing. I have.

Ever see a wire bucket that you carry golf balls in, to the driving range?

Now, it works wonderfully on the golf balls, attempt filling it with
water and you find it leaks! Same thing with that bell jar. You simply
can't pump the ether out ...

Indeed, the bell jar, being made of the large molecules of our matter
would appear as a very large screen, or even like a layer of gravel to a
liquid/gas, to the quantum-structure-nature of ether ...

Yep, the solid state and basic computer theory were there too, but I was surprised that they used a schematic of an RF tube amp for diagnostics purposes. I was sure that they were going to use solid state equipment for diagnosis. I was wrong. As it turned out, tubes are always easier for me to figure out, so it ended up being a plus for me.

The Advanced Class amateur license test was definitely the pinnacle of amateur radio technical testing, but I didn't feel it was up to the 2nd Phone test that I took for the General. In fact, I even found a few mistakes in the Advanced test.

The Extra Class test (I took it in 1985) did include a question or two that required some trig, but I figured out the answer in my head before finishing the equation. It was obvious that the conjugate impedance was going to be

capacitive. There was only one answer with a -j, so it was obvious that that would be the correct answer.

Nixie tubes. Ah... nostalgia. I've got several boxes with Nixie
tubes (HP5248M, HP5246L, and some home made junk). I think I paid
more for the printed manuals than for the counters and downconverters.
The usual problem with ancient hardware are the electrolytic
cazapitors. If you have an ESR meter, test them to see if they have
"dried out". If everything looks like it's working (display lights up
and digits change when thrashing the buttons), then it might be the
time base oscillator or dividers. Try an external time base
oscillator in case the crystal has quit.

>I am

Photo of the counter at bottom of page:
<http://www.k5cm.com/k1ggiFMTMethod.htm>

General Radio morphed into GenRad and was bought by Teradyne. The
test equipment division went to IET Labs:
<http://www.ietlabs.com/Genrad/index.html>
The have a few manuals online:
<http://www.ietlabs.com/pdf/Manuals/index.html>
but not the GR1192B. Send them email as I'm sure they have a printed
copy in the archives that only needs to be scanned. Maybe just the
schematic and block diagram.

I make it a habit of buying or downloading the manual for literally
every piece of test equipment that I use. I find myself repairing the
old equipment all too often:
<http://802.11junk.com/jeffl/pics/home/slides/lab.html>
Note: It's a lab, not a museum.

>Just got mail from K7ITM offering to supply the Eico coil info. Thanks
>for the Heath data.

Cool. One question. Is the frequency range of the Eico the same as
the Heathkit ranges that I listed? I'm curious.

Power supply was also my first thought, but Nixies light up and if I
try hard, I can change some digits. Time base fault sounds like a
good bet. Thanks for the hint.

I don't think 20-30 year old HP's are at all museum pieces - they are
still in their prime.

> Cool. One question. Is the frequency range of the Eico the same as
> the Heathkit ranges that I listed? I'm curious.

Eico 710 has 8 coils starting below AM BC band:
L1 0.4 - 0.7
L2 0.7-1.38
L3 1.38-2.9
L3 2.9-7.5
L4 7.5-18
L5 18-42
L6 42-100
L7 100-250

If the vacuum pump was evacuating ether along with
air molecules, the clock would also be evacuated.

An opaque solid is a medium that will pass sound but
not light. A vacuum is a medium that will pass light
but not sound. One cannot evacuate ether using a
vacuum pump.

In that evacuated space in the bottle, two conducting
plates will be pushed together although connected to
nothing. What does the pushing if not something in
the vacuum medium?

Consider that the ether may be made out of exotic dark
matter capable of occupying the same space as the glass
in the jar, indeed providing the very structure that
allows the glass to exist in the form that we perceive.

Could be, but can be explained without "dark matter" ...

Lead is a very dense material, we use it as shielding against atomic particles. Take a chunk in your hand and contemplate all those molecules of lead you are holding. Then realize if that block of lead were enlarged to scale, to where an atom of that lead were the size of an orange, and you are standing next to one atom--the next closest atom would be about the length of a football field away. This leaves plenty of room for quantum material to pass though easier than wind passes though a chain-link fence ...

Actually, I am far too conservative in this example ... this:

"If a drop of water were enlarged to the size of the earth, each atom in it would be about the size of an orange. Yet most of an atom is empty space through which the electrons whirl. The nucleus itself occupies only one million-billionth of the atom's bulk. "

From here:

http://www.time.com/time/magazine/article/0,9171,792294,00.html

"Our matter", being used as a "bottle" for ether is a "SERIOUS JOKE!"

I picked up on that too. If you didn't know what was going on there, you would be left drudging through a math problem.

The thing about Trig was having to memorize all the substitutions in order to poke the problem into a manageable calculation, or you wind up losing precision. If that happens, you wont have the clear cut answer for the multiple guess.

In some ways I miss tube equipment. Now I have to deal with surface mount technology. Even for a resistor, I risk putting a soldering iron up my nose while squinting through a loupe. I just dread the idea of replacing a chip with 100 legs or more. In the 70's you had to know tubes and everything else too because there was so much transition. Ham Radio magazine was my best friend, and it was an opportunity to learn the discrete versions of complex stuff like synthesizers and various issues that had to be overcome. It's all easier now. If you can figure out what a controller is supposed to do, all you have to do is make sure the rest of the components can comply. But there is so much offshore cheap junk now that almost everything is worthless to fix but cheap to modify. Except for industrial controls and things like that. But now customers are just trained to throw stuff away on a bigger scale. I get the idea that We as American citizens are not allowed to know technology any more.

AT-271 Fishing Pole Antenna. ..Miltary Collapsible Antenna [
Picture 2]

This portable antenna can be used for the top section of a Vertical
Antenna OR Horizontal elements for an Antenna System such as the
Buddipole tm ..... A Great QRP / Portable Antenna weighs only 400
Grams [14 Oz] and measures 104" extended yet only 14" long when folded.
The construction is the same as is used for sectional fishing poles. Each
of the 8 hollow tubular metal sections has a plug one one end and a socket
on the other end. All the sections are connected by a string made of either
a cloth or metal cord. At the bottom of the base element there's a spring
inside the tube to tension the cord. Some units may use an elastic
shock-cord material. This way all the elements are kept in order when
they are disconnected from each other and are held together when assembled
into a 104" [8.6 Ft] long antenna. When the elements are folded or
disassembled the package is only 14 inches long.
The base has a male 3/8-24 thread which is the same as is used on most Ham
Radio and CB antennas. Some sort of spring base could be used when this
antenna is used because the hollow antenna elements will "fold" if too much
force is applied to them.
These units are in Like New Condition.. Sold AS-IS but will not be DOA.
Have access to more...ASK!

$30 USD + Shipping

These things are the best. They are stereo so you get depth perception.
They are cheap and the optics are very good. I can read the numbers
on parts the size of a grain of salt and I'm 59 years old. I have no
SMT dread.

One place I worked at stole mine right off the wall before firing me
"because they couldn't throw me in jail for anything". I simply reported
the theft to the FCC and they gave me a new certificate with a new number.
Ever since then, I would only display a copy stamped COPY, but I won't even
do that any more because some one might try to use it. Someone tried that
once and got caught. Stupid is trying to send in a bogus application to the
FCC. Some one tried that once and FCC mailed it back to me asking if I knew
anything about it. Ye haw! It's like going into a doctor's office for an
examination and telling them you need the prescription "for a friend". It's
like pulling a gun on a cashier and saying "I don't want to hurt anyone".

It's probably a simple divide by 10 divider chain. Should be easy to
troubleshoot. Since it probably doesn't work on any range, it's
probably somewhere between the clock oscillator and the first digit
counter. This should be easy (famous last words).

Incidentally, I bought an HP5334A counter on eBay. When plugged in,
it displayed an error messages that indicated the clock section was
dead. I got a really good price on it, so I decided it was better to
fix than to return. I didn't have a schematic yet, and none could be
found to download. After replacing the clock oscillator and the hex
inverter that was acting as an oscillator, I eventually discovered
that the internal/external toggle switch was open. Sounds simple but
this trivial troubleshooting exercise took about a week.
Moral #1: If it moves, it breaks (especially on old equipment).
Moral #2: Simple problems take forever. Complex problems are easy.
Moral #3: That which is most obviously working, beyond any need of
checking, it usually the problem.

>I did get to ietlabs site in my first searches. Never thought of
>mailing them for a scan, though. I'll give them a try.

It will probably cost you some money, but methinks is worth the
effort.

I'm sitting on a fairly complete collection of Intech marine radio
service manuals from the 1970's. One of my customers has a Canon
Imagerunner 5000 copier and scanner combination that does a totally
impressive job of scanning manuals (hopper feed, de-collating, scan to
PDF, etc). At about 2-3 hours per manual, this is a major project.

That depends on what you're doing. For tinkering and experimentation,
it's good enough. For design projects and consulting, it's

inefficient, insufficient in many ways, and barely adequate. For
example, using a digital camera to obtain a spectrum analyzer image is
rather clumsy with my cardboard hood.

Sure, Why not just spray paint the inside of the jar? Or use Houdini's
black cloth. Experiments like that prove that "medium" can only tend to
hinder photons. Hence photons travel best without ether. How does ether
affect the velocity factor of light?

Can't find my ether pump anyway, so we have do these experiments virtually.

Modern elevators use AC induction motors with a variable speed drive.

You've described a key test taking strategy that applies well beyond the
FCC license exams. No licensing authority requires 100% scores, and they
generally specify the distribution of questions among subjects. (this is
true for pilot exams and the professional engineering exams, as well).
One can reasonably take a strategy of spending your study time to get
perfect score on the parts you know and accepting what you get on the

parts you don't. Overall, I believe that the lower "stress level" going into the test knowing that even if you screw up the small number of questions you don't know, you can still "pass", is an overall benefit.

This, is, of course, why you have behind the wheel driving tests, have to have an examiner check ride, or reference letters and proven experience for all those licenses. The folks giving the test KNOW that you can't possibly test everything.

Chuckle. That like that happened to me, twice. I worked for a communications shop where I was the only one with a license. After I left, they continued to use my license number or repair logs for several years. When I worked for a radio manufactory, they made a rubber stamp with my license number and continued to use it for several years after I left.

At one point, I let my license expire because I couldn't find it for a few years after moving. I had to take all 4 elements plus radar endorsement again from scratch. I passed 1, 3 and 4, but messed up from overconfidence on element 2. That meant that I had to do all of it again in a month. This time I studied and passed. To save on gas and parking in downtown San Francisco, a small group of techs and engineers went together. We had all studied the latest semiconductor and radio technology that we worked with every day. However, the test was exactly the same as the one I had taken about 10 years previously. Tubes, dynamotors, Marconi antennas, Faraday shields, and other technology from the stone age. A few of the techs failed the exam because they had never studied or worked with a tube radio.

>Ever since then, I would only display a copy stamped COPY, but I won't even

In theory, that won't happen with the ULS system and FRN number as long as your password is secure.

>Some one tried that once and FCC mailed it back to me asking if I knew
>anything about it. Ye haw! It's like going into a doctor's office for an
>examination and telling them you need the prescription "for a friend". It's
>like pulling a gun on a cashier and saying "I don't want to hurt anyone".

I haven't had that problem. A friend that runs an avionics shop casually mentioned that about half of the GROL licenses he sees are counterfeits. He says they seem to use random license numbers, which are easy to verify with a ULS web search. Why they bother is beyond my limited imagination.

Incidentally, identity theft, or rather identity borrowing, is why I don't post my resume online. I've had to deal with several attempts

at impersonating me or borrowing my history on job applications. None were financially or professionally detrimental, but the potential is there.

I had to take a test for the FAA once that the prep material took you
through all kinds of cr stuff that I studied for two months.
When I finally took the BIG test that my job depended on it was ALL
about decibles. The two hour 50 question test took me twenty minutes
and I never picked up my calculator. About all you had to know was 1db
was 20% 3db doubled or halved and every 10db
was 10 times and you pick the multiple guess answer. I remember the
guy giving the test thought I had given up and turned the
test in after only 20 minutes .He certainly was surprised when he

found I ACED it.The people that failed it all knew what they were
doing
They just got bogged down in the crank and grind of the math.

> Can't find my ether pump anyway, so we have do these experiments virtually.

Yeah, beginning there would be good, baby steps, at first ...

In the same way air affects the speed of sound, it limits its speed.

In some common units:

670,616,629.4 miles per hour.

983,571,056.4 feet per second (roughly one foot per nanosecond.)

186,282.397 miles per second.

I think the particles of a photon pass though the ether unhindered, why?
Now that is part of the whole question, isn't it ... perhaps it does
really "travel" at all ... there is that "odd statement" by Einstein,
motion cannot be held against the ether, for any logical observation.

Ether, apparently, is a true "lossless media" in the propagation of
waves ... well, that is how it appears from observation.

Having received some very good advice about the Carolina Windom, I now ask a question to which I THINK I already know the answer.

This particular version of the CW OCF dipole uses 300 ohm twin lead feedline terminated after 33 feet to a 4:1 balun. Richard warned of significant risk of RF on the outer (inner?) braid of the coax.

I've never read of using a 1:1 unun right after a 4:1 balun to minimize RF on the outer coax.

My thinking is that the 4:1 balun acts as a voltage type and will do nothing to ameliorate this. So, I will put some ferrite rings or snap on ferrites just past the 4:1 balun on the coax.

Does this sound like a reasonable solution?

> John
> AB8O

If you use a 4:1 Ruthroff, it would be a voltage balun ... if you use a 4:1 Guanella it would be a current balun ... the 1:1 current balun is probably more useful behind a Ruthroff ... but hey, once you have tried all these possible combinations, you can speak from experience! <grin>

If going from 300 ohm to 50 ohm, perhaps you would choose a 6:1. Or, just go with the 4:1 now and when you need some diversion, later, try the 6:1 to see what improvments can be had and if the loss in this design is acceptable to you ... etc.

Anyway, in this document is a 6:1 (actually 6.25:1, resulting in 312ohm to 50 ohm) made from two 4:1 baluns (I would think Guanella ununs ... the 4:1 can be made from two 1:1, each wound on the opposite side of toroid core, reversing coil directions on one side. This could also be accomplished with 4 ferrite rods ... a 1:1 balun wound on each rod, two rods combined to make a 4:1 balun, then these "two units" combined to construct the 6.25:1 balun ...

A while back I did some pretty careful measurements of an OCF dipole. I found that ferrites were required at both the feedpoint and at one or more places along the feedline. The ferrites at the feedpoint suppress the conducted common mode current (which is actually forced to exist by the voltage balun). But the asymmetry of the antenna results in common mode current being induced onto the feedline by mutual coupling to the antenna. This isn't a problem in a symmetrical dipole if the feedline is positioned symmetrically relative to the antenna, since the currents induced by the two equal halves cancel. But the OCF dipole can result in quite a lot of induced common mode current.

Ideally, you'd put at least a second bunch of snap on cores about a quarter wavelength from the feedpoint. But one of the main reasons people use OCFs is for multi-band operation. So the thing to do is to place the cores for maximum effectiveness on the band(s) where you have the most trouble -- the common mode current also depends on the feedline length and position, and will vary considerably from band to band even if you do nothing.

My opinion is that users of OCF dipoles are just about always going to have to deal with some amount of common mode current, and the best you can do is reduce it to a level you can tolerate.

Roy,
What's your opinion on the 4: or 6:1 balun between the 300 Ohm line and the coax? I see no reason whatever to think that the impedance coming off the 300 Ohm line is anywhere near 300 Ohms. Also, where is it written that a 50 Ohm balun will work at, say, 2000 Ohms. The ferrites as you suggest will clearly work if you use enough of them.

The reason for asking this is that a friend is in the process of putting up a 75 m dipole, which he only plans to use on 75 m. Everybody is telling him to feed it with ladder line going to coax through a balun. Why in the world would you do that?

Cecil
In the version I am putting up, the 4:1 balun is at the bottom of the
twin lead feedline, so the feedline can radiate.

Man, whatever you are on, I'd try it once, in the mountains, on a
weekend, but only if medical science could guarantee there wasn't
permanent brain damage or flashbacks--and it wore off shortly!

Maybe a twelve-step program?; have you considered that?

It is possible to consider that as a possible explanation provided that the hypothesis of exotic dark matter can ever be shown to exist physically, which it can't. It can be used hypothetcally as a possible explanation for the alleged expansion of the universe, which originates from observations using our Hubble peep hole, from which can see a only tiny portion of the total volume of the universe, backwards in time. For that hypothesis to be true, of course we must verify that alleged exotic matter, which cannot be observed, has a negative gravitational force relative to physical mass, something not intuitively obvious; this Hubble observation is where the advocates of exotic matter get their most support. And here we are putting the cart one light year ahead of the horse by considering that it is, or may be, the so called ether for light. Other plausible hypotheses such as an alternation of expansion and contraction cycles, possibly as a damped waceform, do not depend on the abstraction of exotic matter at all.

That would be the total sum of all photons that have ever passed
beyond the event horizons of all black holes in the universe. That
might turn out to be quite a few photons.

By the way, do black holes swallow ether which passes beyong the event horizon of a black hole? That doesn't make sense since light *enters* the black holes due to high force. Then the ether must remain intact on both sides of the event horizon. Might Einstein have been talking about the ether of being the FORCE of gravity itself (in our point of reference), which would be an abstract ether, not a physical one?

Sorry, that is incorrect. It has been shown there is more
matter associated with galaxies than we can see. The part
we can see is thought to be about 5% of the universe. Dark
matter possesses conventional gravity and apparently makes
up about 30% of the universe.

> For that hypothesis to be true, of course we must
> verify that alleged exotic matter, which cannot be observed, has a
> negative gravitational force relative to physical mass, ...

Sorry, that is incorrect. The thing thought to be responsible
for the expansion of the universe is Dark Energy causing an
expansion pressure. Dark Energy is thought to account for
65% of the universe.

I don't consider black holes to be outside of the universe.
In fact, massive black holes are the opposite of "absolute
nothing". They are so massive, they have collapsed the
structure of space, i.e. the ether.

ltdoc@yahoo.com wrote:
> Is this OCF dipole a single band antenna or a multiband antenna?
> - 'Doc

It is alleged to be a multi-band antenna. Assuming that
the standing-wave current is 90 degrees out of phase
with the standing wave voltage, one can actually calculate
an approximation for the feedpoint impedance by dividing
the standing-wave voltage by the standing-wave current at
the feedpoint. With an OCF, the feedpoint impedance will
always be lower than Vmax/Imin and always higher than
Vmin/Imax and thus provide a reasonable SWR for 450 ohm
ladder-line.

The free demo version of EZNEC available from
http://www.eznec.com
will provide a reasonable guess at the feedpoint impedance.

Here are what EZNEC 4.0 says about the
feedpoint impedance of the following:

------------83'----------FP-----47'--------

3.8 MHz, 85.5+j98.5 ohms, SWR(300)= 3.9, SWR(450)= 5.5
7.2 MHz, 177-j181 ohms, SWR(300)= 2.5, SWR(450)= 3
10.125 MHz, 3569-j102 ohms, SWR(300)= 12, SWR(450)= 7.9
14.2 MHz, 96-j357 ohms, SWR(300)= 7.7, SWR(450)= 7.7
18.14 MHz, 797-j911 ohms, SWR(300)= 6.3, SWR(450)= 4.4
21.3 MHz, 933-j1239 ohms, SWR(300)= 8.8, SWR(450)= 6
24.95 MHz, 218-j652 ohms, SWR(300)= 8.5, SWR(450)= 6.7
28.4 MHz, 757+j1019 ohms, SWR(300)= 7.4, SWR(450)= 5.1

As you can see, the myth that this antenna has a 300
ohm feedpoint impedance is just an old wives' tale but
it does have reasonable SWRs when fed with 450 ohm
ladder-line.

Cecil,
I sort of thought that this OCF antenna was typically used for a multiband antenna, that's typically the 'idea' behind using them. Keeping that 'thought' in mind, how can you 'optimize' this multiband antenna for one particular band without 'de-optimizing' it for others? That seems sort of going at it from the wrong direction, why not use an antenna that works well for the particular band of interest. Oh, I know that assumes that you can have more than one antenna, which isn't always the case. So having an 'un-optimized' antenna is what you'll end up with in most (if not all) bands except for one. Which is the 'fault' for almost all multiband antennas. Isn't it?

Given the SWRs that EZNEC predicts, feeding the OCF
at a current maximum point causes the XMTR (or tuner)
to see the following resistances looking into the
ladder-line.

3.8 MHz, 129 ohms; 7.2 MHz, 120 ohms; 10.125 MHz, 37.5 ohms;
14.2 MHz, 58 ohms; 18.14 MHz, 71 ohms; 21.3 MHz, 51 ohms;
24.95 MHz, 53 ohms; 28.4 MHz, 61 ohms

Let's say you wanted to optimize for 40m. You would
choose a 450 ohm ladder-line length of 67.5 feet and
expect 120 ohms looking into the ladder-line. Use a
tuner or transformer for a perfect match.

> Oh, I know that assumes that you can have more than one

Not for this one: http://www.w5dxp.com/notuner.htm
That antenna system is efficient on all HF bands.
It is fed with 1/2WL of ladder-line on 80m and 3/4WL
of ladder-line on 40m. Also appropriate lengths of
ladder-line on all other HF bands. The ladder-line
length averages around 100 feet.

It's amazing how far into space people will go without even stepping off the planet.

Don't get me wrong, It's good to explore in the best we can, but one thing brings me back to reality. No one of us seems to be able to keep straight in our heads, all of the details of all the theories, observations, problems and their interdependence and conflicts. It seems that every conclusion presented that I can have hope of researching in great enough detail, reveals leaps of faith.

Reminds me a whole lot of the Psychology and Philosophy courses I took to round out my transcripts. All the GREAT GENIUSES in those fields got tunnel vision and went way out on a limb even to the point of developing their own dialect. The lesson learned of all that, was that humanity is so versatile that no one could point to one theory that held up in the broader range of human experience.

What does that leave us with? Tools that can be applied if we know where they can be used, but only if they hold when we put work to them.

The end result though, is that humanity is so versatile

> - 'Do

Seems to me it's not "optimized" for any band, but is just a fudged radiator fed by ladder line, matched with a tuner or maybe a pi-net without too much line loss. You can fiddle with it to your hearts content, but in the end will it load up where you want it to and will you get out? It would be nice to have an antenna analyzer to have some indication of YOUR installation as you fiddle. Obviously you will have trouble using any of the modern internal ATUs.

Years ago, I threw one up but fed it with coax. It didn't work so I rebuilt it as parallel fed Dipoles for 80 and 40m.

Thanks for the NEC output, Cecil.

> Why in the world would you do that?

As you suspect, the impedances encountered by the transformer on some bands are wildly different than its nominal design impedances. In the one which I carefully measured, the result was no surprise. When the antenna impedance was substantially different from 300 + j0, the transformation ratio wasn't 6:1, and the transformer added series and/or shunt reactance, sometimes a pretty large amount. And this was the case on most bands.

This isn't to say that an OCF dipole can't be fiddled until, radiating feedline and all, it manages to present an acceptable SWR on several bands. But when it does, it's not working at all like predicted by a simplified analysis which ignores the strong feedline coupling and very non-ideal transformer effects.

S A s are usefull for antenna hobbyists. Some twenty years ago there
was a DIY S A that used a t v tuner in
Ham Radio. Moving forwards some twenty years and most hams have
computors and there are 2.4 Ghz
spectrum analysers out there as well as audio set ups for computors.
So what is available today for hams
in the HF BANDS? There are a lot of older type audio S A s on E bay
but I haven't heard of anybody modifying thoseand with most having
computors it would seem reasonable to think that there were components
available that could performn between audi and 2.4 Ghz. So has anybody
seen any modern type DIY spectrum analysers
around for sale or kits? I have 141t and other types of SA which now
are considered bulky and I would really like something smaller or say
modify something like a audio setup as a project.

I have switched my balun designs to the one in this URL, Figure 4 -
Improved 4:1 Current Balun, page 3:

http://home.earthlink.net/~christrask/Trask4to1Balun.pdf

Can be used balanced, or forced to unun fashion ... bandwidth becomes
increased (and, it "just works better for me!")

But, what works for you is the most important, always ...

Art,

Funny that you should ask, because the October 2008 QST (just arrived a few days ago) has a computer-based DIY spectrum analyzer project. Doesn't look too difficult: a couple of dozen parts and a software program that's downloadable from the ARRL web site.

These days, the scanning receiver part isn't the hard part. It's
calibration and user interface.

For instance a Icom PCR1000 makes a fine HF,VHF,UHF spectrum analyzer,
although the resolution BW steps are limited and sweep speeds are limited.

What you get with a "real" spectrum analyzer is a fairly intuitive user
interface (with knobs!), well characterized and consistent RF
performance over a wide variety of operating conditions, and
calibrateability (i.e. stable and repeatable operation)

It's sort of like the difference between a real oscilloscope and a sound
card in a PC with an oscilloscope program. The real scope probably has
wider applicability, more options arranged in a systematic way, etc.
But for some applications, the soundcard is just fine.

Audio spectrum analyzer (free):
<http://www.sillanumsoft.org>
I use this one on my laptop for audio generating and testing. Try to
get a 96Khz sound card or dongle as the typical internal laptop sound
card is really marginal. No RF, no antenas, but good for audio.

Look into SDR (software defined radio) projects. Most of them will
also act as a spectrum analyzer. For covering bands above 30MHz, use
a mixer and a signal generator:
<http://www.rfspace.com/SDR-14.html>
I really don't know much about these but they look interesting.

Now, if you have a sizeable bank account, one of the various Anritsu
hand held spectrum analyzers are really nice:
<http://www.us.anritsu.com/products/ARO/North/Eng/Spectrum-Analyzers.aspx?lc=Eng&cc=US&rc=
ARO&cat=1&cat2=2&cat3=5&cat4=0>

There are also a large number of hand-help CATV spectrum analyzer
available if you want portability. I've only played with a few, so I
can't offer any useful recommendations. They usually don't have
sufficient resolution to seperate HF stations.

Incidentally, in order to use a spectrum analyzer for antenna testing,
you'll need a directional coupler (or VSWR bridge) and an RF sweep
generator.

I showed how to optimize an OCF for a single band, e.g.
40m. If the 50/120 ohm transformer is link coupled, it will
cause a common-mode current node at the transformer on 40m.
Any antenna system can be optimized if one knows what they
are doing.

For instance, a shunt 1000 pf cap at the twinlead to coax
junction will optimize a G5RV for 75m.

> But for some applications, the soundcard is just fine.

I have seen spectrum analysers the size of a hand held volt meter,
cost around 2 to 3 K
that tells me that the science is there and the chips are there. When
I see kids jumping their fingers all over the place with their hand
games
they have found a way around the knobs and wh
istles and bells so us old folks had better change up a gear. I just
want to see the shape of my transmission signal plus an idea what
bands are busy and which ones are not. For accuracy I can put a signal
on that of the SA and read out the frequency
on my radio. I do not want to replay my work years all over again!
Regards
Art

I bought the 300 ohm feedpoint myth when I was at Texas A&M
in 1958 when I didn't know any better. I had an OCF fed with
300 ohm twinlead fed through a 6:1 air-core Heathkit balun
driven by a DX-40. The results were amazing to me at the
time. Now I know the pi-net output of the DX-40 would achieve
a match to almost anything and I should have been using a 1:1
balun. The Heathkit balun didn't have much loss and the 300
ohm twinlead didn't have much loss. I have no idea what the
actual impedances were, but losses were minimized and the
system successfully worked the world at the height of the
most active sunspot cycle in recorded history.

Adding a bit to Jim's good comments... just because spectrum analysis can be done with fewer and smaller parts than you needed a few years ago doesn't mean you can get really good performance in a tiny package. It's still pretty tricky to keep residuals, spurs and distortion very low while providing the amplitude and frequency stability that Jim mentions. These days, low phase noise is also a big benefit, since RBW can be very low.

To me, one of the biggest advances in spectral analysis in the past few years is the ability to get very decent dynamic range while digitizing a significant bandwidth, meaning that you can look at a whole bunch of signals all at the same time, and not miss transient events because you were scanning a different range when the event occurred. A side benefit is that a properly done digitizer has extremely good linearity: you can accurately measure amplitude over a wide range of signal levels. It's quite possible to digitize the whole HF range with very respectable dynamic range; the display then becomes a matter of digital signal processing--and there are chips capable of keeping up with the high data rate while providing narrow frequency resolution over large chunks of, or even the whole, digitized bandwidth. Digitization also makes keeping phase noise low relatively easy, if you don't have to also do analog frequency conversion--and even there, if you can do the analog conversion in only relatively large frequency steps, it's a help.

Cheers,
Tom

Of course but I'm too lazy to run the numbers if it isn't my project. My favorite single band wire antenna is the Dipole. How is OCF an improvement? I also liked my Inverted L made out of a homebrew 9' bug catcher mobile antenna with 25' horizontal clip on extension for 40/80 and clip on shunt caps at the mobile mount. Works well in the campground.

Keeping the antenna matched to the coax DOES make a difference, considering coax losses.

Art, with your knowledge of antenna theory I'm surprised you'd ask this question. You should know that whenever energy is taken from one direction it is directed in another--none is lost due to cancellation. If you integrate all the energy radiated in all directions from a given antenna system (neglecting losses due to attenuation) it will be the same whatever the arrangement of the radiating system when fed with the same power.

David has a habit of turning everything upside down and in the absence
of comment usually reserved for me
I have to assume that David is correct in every thing he states
because of the silence of others. So I ask a question
which is upside down on the assumption that David will turn it around.
You must remember that I see electrons of the same polarity which
cannot collide
so you shouldn't be surprized at any thing I say. Reading today a book
on gravity I read a statement that if a moving particle has a magnetic
field
then one can apply the title of radiation as both a particle and a
wave! No wonder everybody is screwed up on this group. As far as
cancellation is concerned that refers to direction where another
vector at right angles takes it's place per Newton. There is a big
difference between cancellation and destruction the latter does not
exist per Newton. You can put that in a book and call it revision 2.

Cecil
I do not view Newtons law that way at all
First of all," energy cannot be created or destroyed " which puts"
destructive" as an obsolete word
When Newton espoused his action and reaction law he had equilibrium
very much in mind
His law refers to an "action" as opposed to a "force" so when he
refered to an action it was to the neutralization of force
which in his thinking was stabalization or equilibrium . He then went
on to talk about an equal and opposite reaction.
He was referring to a similar action at right angles to the line of
the first action. Thus, if you pull a piece of rubber thinning or
"necking" occurrs because of the "reaction" required for
stabalization. In a helicoptor you have a big rotor on top that is an
"action", the reaction that Newton talks about is the other action
needed for stabalization which is the rear rotor that is at right
angles to the main rotator. Newton looked at things as three
dimensional and not as a single plain of freedom as with two colliding
forces. He was very specific in stating "action" and not the term
"forces" the same fashion as Maxwell and others refer to a static
field and a dynamic field. From my mind destructive interference
refers to a frictional action that is visible to the eye.
It is these mangling of words in the different sciences that allow
people to thinks that all sciences have their own laws without
connection to a Universal Law which by necessity must be founded on
equilibrium. In our Universe you cannot have a immovable contact
unless there is a interlocking or frictional force. In other words,
two forces cannot travel in a straight line towards each other. Both
force paths are curvacious with respect to the Universe such that the

impact is always one of deflection. But then Cecil you knew all that didn't you !
Different subject Einstein viewed ether as unthinkable because of equilibrium which is the foundation of boundary theory where all forces within the boundary equals the forces outside the arbritary boundary. Einstein realized that if the forces were not equal or in equilibrium the field must change from a static to a dynamic field where implosion is the only way to re establish equilibrium. Plain common sence don't you think?
Best regards
Art Unwin KB9MZ
Best regards
Art

No problem. We'll do it differently and easier. Here's the NEC2 file
for a 145MHz JPole for stolen from the 4NEC2 samples.
<http://802.11junk.com/jeffl/crud/J-ant.nec>

I just discovered that the conversion program from .MMA to .NEC will
generate a perfectly usable .OUT file, but not a .NEC input file. I'm
probably doing something wrong, but I don't have time to debug it
right now.

Note to self: Make an index of .NEC files. It's becoming difficult
to find specific antennas.

I couldn't find any documentation as to the program limits. As I understand it, MMANA-GAL has a stripped down NEC2 engine. 4NEC2 and EZNEC use the full NEC2 engine from Lawrence Livermore Labs. I'm not sure what you're building but allow me to offer a clue. I recently threw together a model of a truly ugly tower with about 8000 segments including about 2000 pattern lines for various grids and reflectors. After about 14 hours running, my PIII/933MHz finally spewed out a result (that told me that I goofed and had to make corrections). I dragged home a P4/2.8GHz with hyperthreading, which took about 8 hours to run. This was getting ridiculous, so I dragged the program and model to a customers office, and ran it overnight on his P4 2.8GHz dual core, 4GB RAM, 1333MHz FSB, SATA2 drive, etc. It doesn't get much better. It ran in 3 hours.

The optimizer isn't much better. It will automagically tweak dimensions to meet a pre-defined set of criteria. If you set the final criteria too close to perfection, you may get an answer after the next ice age.

Anyway, I suggest you use a machine with lots of horsepower and start with EZNEC, 4NEC2, NEC-WIN, MMANA-GAL, or other modeling program using some of the sample files included with each program. Once you have figured out how to manipulate and modify those, you can step up to more complexicated models (such has the giant mess I stupidly created by throwing every piece of metal on the tower into the model).

That's not a sunspot. More like a sundot. I wonder if there's a
minimum size to be considered a sunspot?

Sunspot 1002 was there for about that last 2 weeks, but now seems to
have disappeared.

Thanks for the effort Jeff, but for some reason it doesn't seem to be compatible. It won't open as an NEC file and I also tried giving it just an NC tag. The closest I can get is importing it as a card deck, but it says it has errors, and when I look at the code, it looks totally different from other formulas that do work in the app.

Art, it does have variables... I don't know if the segments are unlimited. It seems to work great with the included files. Normally I'm pretty good at this stuff. I can do my own html and some other code stuff, but I'm just having difficulty getting a grasp on this for some reason. I did find a tutorial for NEC and read the whole thing, but it didn't help much. I guess I'm not great with the scientific stuff.

Can you read the .NEC file as a text file with an editor? I might
have tossed in a few extra carriage returns, word wrapped it, or
something equally stupid. Maybe some extra characters at the
beginning or end?

>It won't open as an NEC file and I also tried giving it

An NEC file is a card deck. I have a Mac Cube with OS/X sitting in
the office. When I have time (which means after Sunday), I'll see if
I can feed it to cocoaNEC and see what breaks.

To work with an SA on antennas you will need either a
"noise generator" (modern method) or a tracking generator
(old method) which can control the SA.

better go for a scalar analyzer or if you can afford it,
get a vector analyzer

It is true, but that doesn't mean or prove that any of the TOTAL radiation has been "lost." It has merely been re-directed to produce some maximum value in one or more directions, and some minimum value in others.

Think of squeezing an inflated balloon. No matter what is its final shape, the volume of air inside the balloon remains constant.

Below is a link showing this, as applies to an antenna. The area within the directional pattern is the same as if the pattern was omnidirectional.

Maybe these web pages can "shed some light" on this subject.:-)

www.mellesgriot.com/products/optics/oc_2_1.htm

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

When field/wave cancellation occurs, the energy must go somewhere.
In the absence of a load to dissipate it, the FSU web page says it
is "redistributed to regions that permit constructive interference".

If the relative phases of the two superposed fields are greater
than 90 degrees to 180 degrees apart, the resulting interference
is destructive.

If the relative phases of the two superposed fields are less
than 90 degrees, the resulting interference is constructive.

Many words are used in a non-literal sense. Superposition
resulting in destructive interference doesn't mean that
energy has been literally destroyed, just that it has
been "redistributed to regions that permit constructive
interference" (FSU web page).

Hi, it is my webpage:

http://www.covermap.es

Covermap is an application that allows the calculation of propagation
loss of a particular antenna defined by the user.
In covermap you have the ability to see the extension of the radio
antenna (coverage mode), the different coverage cells of positioned
antennas (cellular mode) and get the loss in decibels on a particular
point with respect to the antenna (point to point mode).

David
You have stated that you have the smaller AO program (limited in
pulses) but as
yet you have not proved to anybody that you know how to use it !.
If you insert dimensions for a vertical radiator where none of the
dimensions for XY and Z
are repeatable then the program gives you picture of the weak force
and it's angular direction
.Not only that my friend, it also shows that with the use of this
vector (the weak force remember)
it shows what the position the radiator must take up for maximum
gain !. Drunken vertical indeed!
On the other hand you can continue the mistaken idea that
intercoupling of radiators provides the same
gains as Maxwell who includes the weak force in his calculations for
absolute accuracy.
Remember what I have told you " A radiator can be any size, shape or
elevation as long as it is in equilibrium"
This is contrary to what the experts say that a radiator MUST be
straight, which is absurd.
But then you rely on absurdities.
Your friend
Art

Then there are the discones and LPDAs where size matters.

The bug catcher worked well and still does despite many repairs, 15-40 m by itself. 40 and 80 with the extension. It's a modified hamstick with 4" dia. by 8" hand wound #14 coil in the center with scrap plastic forms. There must be an unwritten law that says only the ugliest projects will work. It was a pipe dream of flea clips, but the goal was to do all matching on the antenna.

I used it mobile with a 365 pf broadcast variable on the mount and a remote operator into the cab. Add a little series XsubL with a flea clip, matched out with the cap to raise the impedance at the mount. The coil would self resonate so 12 and 17 wouldn't work (perhaps a longer stepped pitch later). Shorting around the coil got me 10m back. I would tune for min SWR (actually ALC) and the difference between not heard with an OK SWR and heard well after a fine tuning was repeatable over and over. Even with as little as 15' of RG8x. Worked a lot of DX on the commute back and forth to school. Had no time to do it any where else.

It's shocking how much evidence disappears that doesn't promote someone's
career. It is common knowledge (even a widespread joke) that the public
defender is only equipped to get your bail reduced. The private criminal
attorney however, is well equipped to bleed you out.

The whole system seems to be so jaded and sadistic, that they actually have
more fun screwing the easy meat with something to lose. It doesn't have
much of an impact on the hardened criminals, who are their "good customers",
but scare the hell out of them.

After 9/11, the emphasis has been on terrorists that come over and attack.
I guess the terrorists that live here now are someone else's responsibility.

Nice, but are you using a flat earth model? I plugged in my local zip
code (95060) location, leaving the rest of the values at your
defaults, and ended up with a rather crude coverage map of what I
would get if there were no mountains in the way. I reduced the
antenna height to your minimum of 1.5m, and got something a little
better, but still looking like a very flat earth.

I was hoping to be able to produce something like this:
<http://802.11junk.com/cellular/jeffl/SVLY-PGE/>
as generated by Radio-Mobile software.

Also, if you switch back and forth between "cellular mode" and
"coverage mode", you lose the coverage data from the previous
calculations.

When done, the coverage map is covered up with a balloon with the
aerial number and lat long. Nice but there's no way to get rid of it
without also restarting the program with a new aerial. Also, the term
"new aerial" should really be "new location". The aerials apparently
increment for each new plot, but there's no obvious way to retreive
previous locations or manipulate the count.

If your optimization is just changing a small part of the overall
structure (e.g. the position of an antenna on the tower), then you
should be looking at the Write Greens Function and Read Greens Function
cards.
http://www.nec2.org/part_3/ngf.html

This is how they do things like analyze antenna placement on a ship or ISS.

NEC takes some getting used to, and, the tutorials that come with it are aimed at computational electromagnetics folks, who already understand how NEC works under the hood, and are really looking at "how do I put my problem into a form for THIS particular code".

There's some pretty common "tricks of the trade" used with NEC, like using a network to create a current source (4nec2 does this for you automatically).

Mostly, though, it's just slogging through it the first few months until you get your mind wrapped around the conceptual model.

Start with something fairly simple (but non trivial).. like a multiband dipole or a 3 element Yagi with just wires (i.e. don't start out trying to model the U-bolts and stuff).

A dipole is nice to fool with, because you can put a wire in under it to represent a tower, for instance, and see what effect it has on the pattern. Likewise, you can do something like model your rain gutters or the feedline as a single wire, and see how much current is induced in them.

Like the TAPR TenTec VNA.. very nice piece of gear, but does have a
broadband detector, so it won't work as a spectrum analyzer, nor is it
going to work well in a RF dense environment.

>
> RF

All quite true ,But my reasoning on harvesting is to provide for
maximum return or use.
For a Yagi the radio amateur is interested in the main lobe and it's
xyz coverage.
All the rest is considered "wasted" or providing unwanted interference
If I did not create the nulls between lobes my time of use is then
doubled instead of wasted.
The beam that I am interested in is one that has a single lobe which
I can control in
terms of elevation and beam depth where I am not knocked out because
of radiation
nulls, which is the case for all planar arrays.
Just another reason to focus on equilibrium for radiation formation.
where one can obtain
gain with a single lobe but with a usable lobe width and depth and
uninterupted propagation..
But then, all is known about antennas and if it were possible as the
experts state or
we would have been using such antennas years ago !!!!!
Or as another person stated we don't need a different
type of beam radiation as we already have one!!!!
So by all means crush any and all ideas of change

IIRC a quick flat earth estimate is the square root of 2, times the square

root of the antenna height in feet. That gives an estimate of the coverage radius in miles. :)

Thanks. I haven't done much with the optimizer beyond tinkering to
see how it works. I've never tried the NGF feature, but it certainly
looks interesting. Looking at the above page, I'm instantly lost.
However, I'll be taking yet another medical vacation shortly, so I'll
have plenty of time to RTFM.

Incidentally, the tower in question is at a friends radio site. It's
loaded with a mixture of commercial, FM translator, and ham systems.
There was almost no planning in the tower antenna arrangement. The 2
ton gorilla in the mix are 3ea 250 watt 900MHz paging xmitters, that
are causing problems with the other users. I can't touch their
antennas because they pay the bulk of the bills. There are also some
nulls that need to be moved to placate some of the customers. I'm
trying to first model, and later optimize the location of the other
antennas. So far, simple solutions like vertical isolation and
positioning antennas on opposite sides of the tower from the paging
antennas look promising. Sorry, no photos as the owner wants me to
keep the location secret.

Yep. I just got the same error (after wasting 30 mins doing updates).

"Syntax Error in external declaration: identifier CM"

CocoaNEC can't even parts a CM (comment) declaration. Something is
wrong. I found the examples for CocoaNEC at:
<http://homepage.mac.com/chen/w7ay/Manuals/cocoaNEC/Manual/examples.html>
which work as expected. I figured out that it wants to import a .NEC
files as a "spreadsheet". However, when I try that with the Jpole
file, I get "Cannot open xxxxx. File may have moved or been deleted".
After that, CocoaNEC "quits unexpectedly" and wants to know if it
should stay dead or restart. Lovely mess. I'll work on it some more
later tonite or this weekend. I may even RTFM.

Incidentally, my Mac G4 Cube only has 384MB of RAM, which may be the
problem.
<http://en.wikipedia.org/wiki/Mac_Cube>

>Well, I'll start reading all of that stuff... Maybe it will sink in.

Not if you can't run a simple model with CocoaNEC. Have you
considered switching to the dark side and getting a PC? I haven't
tried running 4NEC2 or EZNEC under Bootcamp or one of the Windoze
emulators on OS/X but that might be worth a try.

2976. How to make an excellent wifi (802.11 b/g/n) antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-09-25 05:39:23 UTC
From: Penang <kalambong@gmail.com>
Message-ID: <8eb6f12c-45d1-4420-9460-73a463e8419b@a19g2000pra.googlegroups.com>
Source record: 21650

My background isn't on antenna making, in fact, my training is in Chemical engineering, not physics.

But lately I've spent a lot of times consuming materials I dig from the Net about antennas, in the effect to learn how to make an excellent (effective?) wifi antenna.

Specifically, my interest is in the "broadcast" type of antenna ... trying to find a way to "extend" the range of a typical wifi basestation using antennas alone (maybe with the help of MIMO antennas), without "range repeaters" or whatnots.

My brain is now fully clogged, and I'm having difficulties digesting all the stuffs that I've gotten.

So I desperately need you help.

Is there a place (a forum, a website, a tutorial, and whatnots) where one can learn about antennas, without having one's brain clogged up, like mine right now?

What's your suggestion / opinion on how to construct an excellent (pair) of MIMO antenna for wifi (802.11 b/g/n) ?

Thank you all !

Thanks for all the effort... With the exception of the app quitting, I
had all the exact same things happen. I could run XP on here, but it's
not worth it just for this. Seems like starting from scratch may be
the only way to go with this app. I'll keep at it.

Yeah, you are welcome.

98% of all WIFI antenna tutorials on the www are bad,
unuseable or simply blatantly wrong. Their objects
(avoid calling them "antennas") have the functionality
of a bare piece of wire, which works also.

So I made a 100% WIFI antenna to have an object for a tutorial.
But it is not one of the broadcast type you requested,
I made a 10 turn 2,4 GHz helix with bandpass stub.

I just moved over to grab the camera for a quickie,
the antenna dropped down to the floor, the tripod
fell over my coffee and the cat jumped into my apple pie.

My scalar analyzer failed last week and is on repair,
so I cannot make the proofing screenshots: 50 Ohms over
the whole WLAN channels 1 to 13 with an SWR < 1,5

(and the stub prevents overload by cellular & TV).

Why is everything that complicated?

w.

Hi Jeff. Covermap is specially thinking for a high antennas (>12 meters). When you do click on some point in the map (with zoom) the application calculates the coverage area in consideration of the terrain elevations.
If you want to position one antenna in the same point that the last antenna, you should to change some parameter and automatically appear a “recalculate” button.

I recommended the help section. In this section there are demo videos and other data like the propagation loss model of the application.

Starting with one or two basics;

- Keep the losses down
- Channel as much of the radiation as possible in the direction you need it

Losses in this sense more come from coax runs and connectors. Keep the run short, dont use joiners and if possible mount the WiFi box close to the antenna. You have to also allow for obstructive losses like trees and buildings. The other path loss is from errant reflections. Moounting the antenna high up in the clear resolves many of these issues.

Radiating in the right direction isnt rocket science in theory. The average "omnidirectional" antenna is actually "all directions" only parallel to the ground. ie you dont waste radiation skyward or warming the dirt! In terms of distance covered though an omni of this kind wont be as good as employing an antenna that "beams" in one direction. Consider this as a kind of flashlight with reflector and you'll get the right idea. In terms of time/construction/distance investment you'll do a lot better with this kind of antenna than an omni, elthough you will need to point them in the right direction. Which one you choose depends on its intended use.

You have probably figured out that the antenna gain figure (in dB) is the measure that is used to determine how much better one antenna is over another. It is a log comparison of the desired radiation direction "strength" vs that of an antenna that radiates eqaully in all directions. An omni however will almost always have a lower gain than a "beam" type antenna. 9 and 12 dB are some fairly high omni gains but "beam" gains can go 15-30dB. The higher the number the greater the range in the desired direction.

So my view.. If you intend one site being fixed and the other movable then you'll at least need an omni at the base site. If you only want a point to point link then a "beam" variety at each end is the way to go. I wouldnt go for "best" but engineer the path/strength requirements to determine the antenna gain needed. If I was making the antennas I'd probably use end fire helixes as they seem to be most forgiving in construction errors vs best gain.

You might want to tell us your end application, distance to cover, movement of sites and so on so we can suggest something a little more finite.

Cheers Bob

Broadcast implies one way transmissions. Wi-Fi is bi-directional.

The common terms are "range extender" or "repeater". These normally
refer to store and forward transmitter/receivers use to extend range
by retransmitting the data. This is roughly how a MESH network
operates. There are some severe limits and compromises to using such
repeaters, none of which have anything to do with the antenna. Ask if
you need details.

>My brain is now fully clogged, and I'm having difficulties digesting
>all the stuffs that I've gotten.

One must suffer before enlightenment. You're doing fine.

>Is there a place (a forum, a website, a tutorial, and whatnots) where
>one can learn about antennas, without having one's brain clogged up,
>like mine right now?

No. Brain damage is a known side effect and complication resulting
from trying to digest the entire field of antenna design all at once.
Just reading some of the posting in this newsgroup should adequately
demonstrate the extent of the damage. I suggest you approach antenna
design in the same manner as eating a loaf of bread. It's done one
slice at a time. If you try to shove the entire loaf down your throat
at once, you'll choke.

>What's your suggestion / opinion on how to construct an excellent
>(pair) of MIMO antenna for wifi (802.11 b/g/n) ?

I suggest you give up immediately and read about how MIMO works.
External MIMO antennas are a problem.

There are two basic types of MIMO. One is called "beam forming",
which uses an elaborate and flat array of internal antennas to
customize the antenna pattern. Major lobes are pointed in the
direction of users. Nulls are pointed in the direction of
interference. The key point is that antennas are internal and
therefore external antennas have no place to plug in.

The other type is called "spatial diversity". It uses multiple antennas and multiple receivers to combine reflective signal paths. In theory, each path is independent and carry an independent data stream. Combining these paths results in enhanced speeds. Note that this form of MIMO is all about speed, not range.

It is possible to attach external antennas to a spatial diversity type MIMO system. However, there are limitations. You can't just install 3 directional antennas pointed in 3 different directions. Pointed in opposing directions, the antennas will simply not pickup any reflections. If there are any long path reflections, the delays will probably be excessive and the data deemed useless. Attaching a single antenna to a MIMO spatial diversity type router will function, but only at 802.11g speeds. Without the time delayed reflections, there's no MIMO speeds.

Anyway, I don't have any suggestions on how to construct an excellent antenna. You haven't specified what you're trying to accomplish, what you have to work with, what is your operating environment, and what problem you're trying to solve. Different types of antennas are designed to solve different problems. Without a clue as to the problem and limitations, it's rather difficult to select a suitable antenna.

Hint: Forget about using "N" or MIMO with external antennas. Unless you're trying to move video, 802.11g speeds are good enough.

Hi Penang

Do you wish to broadcast to all azimuth directions? The antenna design is highly dependent on the angle over which you want to 'extend wifi'. I suggest you read some of Trevor Marshal's writing (Google his name)

I strongle recxommend that you use [router, bridge] at the antenna and use CAT 5 to connect to your computer.

Often gain type antennas already came with the unit. The problem is in putting the antenna where it will do some good. The other problem is in losing signal getting it from the AP to the antenna. You can easily lose any gain from a good antenna in the cable and connectors. On the other hand it is worth that just to be able to put the antenna where it will do some good. If it is any consolation, Cat5/6 is cheaper and faster than the AP itself. Still it is a pain to have to climb and do acrobatics just to push a reset button. There are excellent base station type antennas, hardware and feedline that can certainly optimize a signal for blocks away, but they are expensive and must be properly planned and executed to avoid wasting it all.

This isn't amateur radio so it really isn't on topic. It sounds to me like a business opportunity.

Much research is going on and designs/parameters advanced. These two papers represent the direction this is taking:

http://ceta.mit.edu/pierl/pierl01/10.07111810.pdf
http://www.ece.uci.edu/~ayanoglu/MIMO_MRAA_IEEEAWPL.pdf

However, the DLM (Distributed Load Monopole) antenna by Robert Vincent is an excellent design for such applications.

However, since size is not a major consideration in my external wifi antennas, a conventional 1/2 or 5/8 wave end fed design is what I have implemented, with a gamma feed ...

I use a biquad with a parabolic reflector (from a direct TV sat. antenna) for directional antenna implementations ...

I am following the KISS method (or, Keep It Simple Stupid! -- NO insult intended ...)

David, you just have to be a leader in this. Total reliance on books
or even on wilkapedia
is for the birdes. It is upto you what rock you build your reputation
on.
Going to school only brings you up to date with other peoples
thinking so that
when you leave you don't have to reinvent the wheel. For the
increasing number
of head woblers that are join ing the hobby that is understandable but
for those who sought
education as a means of just making money is really stealing from the
next generation.
Education is meant for the advancement of the human race where
continued scientific
approaches after school was meant to correct the errors of the past
to strengthen the rock
for the next generation to build upon. Denial of progress or the
effort to prevent change is just theft
so that the children have to follow the selfish efforts of their
elders. Change will come with respect to antennas
tho probably after you have gone. You may posses the direction at the
present time of a generation but soon you will be gone
and the human spirit formerly chained by their elders will re emerge
in disbelief of their elders folly who while dwelling in a garbage
can felt safe from intruders, learned to ignore the smell that became
associated with them feeling that they had won the conquest of change
prevention
Your final place of rest will be in a hill amoung friends but without
a voice.
Art

I was trying to be diplomatic and subtle. Apparently, I failed.

On another mailing list, I once had someone telling me that I'm wrong
because 90% of the universe is dark matter or dark energy. Since
these are total unknowns, 90% of everything is therefore unknown.
Therefore, 90% of my analysis must also be wrong. I rather like the
logic.

However, I was serious about taking it slowly on learning about
antennas. To really understand how they work and what they, it takes
far too many diverse diciplines (Maxwell's Eqn, modeling, propagation,
topography, material science, construction techniques, impedance
matching, surface geometry, etc) to absorb it all at once. Also, some
hands on experience is always useful.

It's like trying to recover an intelligent signal out of gaussian
white noise. Despite the best efforts of all involved, the noise
usually wins.

The magnetic north pole being in (or close to) Canada, the Canadians
have a quasi-proprietary interest, and they have one of the better websites:
http://gsc.nrcan.gc.ca/geomag/nmp/northpole_e.php

http://gsc.nrcan.gc.ca/geomag/nmp/long_mvt_nmp_e.php has a map showing
the movement. Indeed, one prediction shows that in 2050 it will be off
the Siberian coast.

Interesting also how it moves around 85km a day, in a diurnal variation.

Among other things:
Many authors have pointed out that the dipole part of the magnetic field
has been weakening during historic times, and that if the present trend
continues, the dipole field will go to zero in roughly 1500 years. Some
people take this to mean that we are entering a reversal.

This might even include you if you were to actually try using one.
But, then the parade would come to an end, as you would see
that there is no free lunch.

> Or as another person stated we don't need a different
> type of beam radiation as we already have one!!!!
> So by all means crush any and all ideas of change

I know you hate yagi antennas, but did it ever occur to you
that the nulls are an advantage to many operators when
receiving. Heck, I bet just as many people use directional
antennas for the receive qualities as they do for any
directional gain. Whacking about 20 db off a west
coast kilowatt can come in mighty handy when you
are trying to hear weak DX in Africa.
Of course, with an equal opportunity dummy load, the
null will be in all directions.
So not only are you screwed as far as directional gain
vs an efficient antenna, you also lack the directional qualities
which many have great use for when receiving.
I suspect your invention using this "new science" will be a
flop at the box office.
Reboot and try again.

Because you insist what you say is true without any proof given.
Not to mention that you refuse to even define how you apply
equilibrium
to your "new science" antenna theory.
And now you think you should rewrite perfectly good antenna theory as
it has been known for quite a few years. Again, without any real
proof,
or even coherent logic applied.

But even worse, you think you have all the answers, and that everyone
else here is either brain dead, senile, fell off a turnip truck last
night,
or they bark at the moon while chasing spiders across the lawn of the
Glendale assisted living center, which BTW is how I often envision you
after reading about 492 lines of your equilibribric/neutrino theory.
But otherwise, disturb not do you.

Actually, I suspect that what you say may hold deeper truths than some realize, perhaps even than you realize ...

If the ether exists in a form some have imagined, if it is possible to couple efficiently to this ether, then a one-inch antenna should be on the same level of effectiveness as a one-hundred foot one.

The "if(s)" is the problem ... and directly relates to that little problem of proof which has been requested ...

The G5RV is a 4-band antenna, 80m, 40m, 20m, and 12m. If
you care about the other 4 bands, don't go with a G5RV.

yes i have built a dipole and it works good with the manual tuner
BUT now my new rig has a built in tuner and of course it wont tune it
the dipole i built was cut for 3.747mhz and works great without a tuner
but with the auto tuner it wont tune anyware but 80mtrs
is there a magic number for a dipole to make it tunable on 80 and 40
thanx

If by searching the web you haven't found a good wifi antenna you should look again as there are lots that will work. If you're wanting to go into business against the major carriers as your equals or competitors, then go back to school for a little longer.....

Polar reversals are now the patent of the Republican party when the
White House tells us the private finance market can't do the job as
well as the government. [If all those companies are slipping into the
big sleep, then the Grand Old Party must have welded the greater fool
model into their platform for this dumpster diving orgy.]

The new compassionate conservative model of unemployment compensation:

1. Have you been indicted this week, such that it keeps you from
seeking work? Skip to #4 if so, but only if you are white,
married, Christian and live in the Hampsteads or can show
mortgages for 5 residences located in no fewer than two states and
one foreign capitol.

2. Have you sought a CEO position this week?

3. List three Board Directors you have contacted this week.

4. If you have satisfactorily answered these questions, pick up
$10million from the public trough and check with us next week.

Remember, unemployment compensation is NOT an entitlement, it is your
special right for having achieved such success in your field of
endeavor. Without your highly productive skills America would be
weaker in the eyes of the world. We know that $10million is a pale
compensation compared to the value you have provided to democracy, but
in these times many have to set aside personal needs for the sake of
keeping the titans of the financial market like PayDayLoans solvent.
Your patience and magnanimity means a lot for the millions of
under-employed that rely on this company.

No magic numbers, sorry 'bout that. Try hanging a 40 meter dipole
from the same feed point as the 80 meter, fed with the same feed
line. Tune/trim for use near the 40 meter frequency you want, then
use that tuner. The same thing will work for any other band you want
to add to it, and will certainly be better than a 'G5RV'.

Often gain type antennas already come with the unit. The problem is in putting the antenna where it will do some good. The other problem is in losing signal getting it from the AP to the antenna. You can easily lose any gain from a good antenna in the cable and connectors. On the other hand it is worth that just to be able to put the antenna where it will do some good. If it is any consolation, Cat5/6 is cheaper and faster than the AP itself. Still it is a pain to have to climb and do acrobatics just to push a reset button. There are excellent base station type antennas, hardware and feedline that can certainly optimize a signal for blocks away, but they are expensive and must be properly planned and executed to avoid wasting it all. There are all kinds of network issues to consider too.

This isn't amateur radio so it really isn't on topic. It sounds to me like a business opportunity.

When modelling antennas and also building them it is obvious that
maximum gain comes about when resistance aproaches zero. Soooooooo
common sence says that the best antenna gain comes about when the anti
resonant point can be easily fed, wellllll thats how my antennas work.
Unfortunatelly, the antenna was resonant on top band
but with a very low resistance so I have to start all over again. The
noise level did increase by 7 S units where modelling showed 9 dbi
gain ! Maybe I should use two radiators instead of the single one. O
well, I have to make changes so the anti resonance point is available
at top band. David, IT IS a topsy turvy world
so I am not available to listenning to the wobbly heads on the radio.
Oh shame for shame

Sorta. I guess you haven't bought any CAT6 lately. I just blew $170
for a 1000ft roll of CAT6 at Home Depot. Add in, wall plates, RJ45
jacks, and jumpers, and I can probably buy 4 or 5 wireless routers for
the price.

Cat vs. WiFi?

Isn't that kinda like comparing a hardwired phone with a cell? One I
can do without, the other I can't ...

Yes that is what I was talking about,With the poles of the Sun showing
no evidence of continuing its rotation
and where the poles of the Earth are accelerating instead of slowing
it could easily be seen as a tranfer of momentum or inertia.
If the Sun becomes passive and the Earth rotates on a eleven year
cycle. then a ice age could appear in the next 11 years!
11 years is starkly different to the 1000s of years that scientists
usually talk about. If the pole continuese this accelleration what is
there to stop it?
Let's hope the Sun shows some activity so I can test my antenna using
the "strong force" instead of the "weak force" and really shake this
group up.
Art

I have found with my G5RV that I still need to 'tune' so that my
transceiver doesn't throttle back in power due to approx. 3:1 SWR on
40/80/20 (and maybe 12). I can also tune 15, 17 and 10. However, as
mentioned elsewhere, it is only good on 80/40/20/12. The SWR on 10
without a tuner is very high and 10 with a tuner is still unusable
(also G5RV is ng for 17m).

I am the only one I know who is doing this, so it may be a risky practice:
tandem tuners.

I have an autotuner in my Kenwood TS-870 and I feed some antennas through an
MFJ tuner set on "BYPASS," usually. If I encounter a situation where the
internal autotuner balks, I flip the selector to the "TUNED" side and get it
close by quickly and casually peaking the received noise (or sigs). Then I
give the autotuner another crack at it and always seems to get a match. The
coax runs are all short and I seem to be getting away with it.

I am putting up more and better antennas ASAP, but there are still some
freqs I can't cover properly, so I cover them improperly :-)

Not MIMO, but many weird looking, but mostly sound, ideas here:

http://usbwifi.orconhosting.net.nz/

"Make 2.4GHz parabolic mesh dishes from cheap but sturdy Chinese
cookware scoops & a USB WiFi adaptor"

By placing the wi-fi adaptor in the antenna, you don't lose radio power in
cables and connectors. You have to be careful about waterproofing,
though.

Jon

First of all, thanks to all for the many wonderful suggestions !!

It's for a community-type wifi network, and I'm cracking my head
trying to figure out a way to make the basestations' broadcast cover a
wider area.

I am reading all your suggestions right now and am trying as hard as
possible to digest them all. :)

Thanks again !!

Since I'm toying with a community-type of wifi network, there are
walls, and foliage, and topologies (hills and valleys) that are
effecting the way the waves work. That is why I am trying to read as
much as possible, while experimenting with an array of weird looking
antennas and putting them in various spots to try out.

The longest (world record?) for a wifi transmission is somewhere at
the 147KM, someone in South America did that. I ain't gonna try to
break it, but would be more than happy -- in fact jumping in hoops !!
-- if I can find a way to make antennas that can successfully spread
the signal. 1 or even 2 miles away.

I'd be reading up the excellent points you and so many others have
given me here, and will try to tinker a bit here and there even more.

Thanks again !!

2.4GHz wireless does not go through hills. If you plan to have
coverage in the valleys, you'll need to have a radio somewhere in the
valley. NLOS (non line of sight) radio can be made to work, but
cannot be made to stay working. It may work for a while. Then,
something is moved, and it stops working. If you want to fill in
holes, look into wireless mesh networks.
<http://www.open-mesh.com>
<http://meraki.com>

I suggest you look into sector antennas, specifically AMOS or Franklin
antennas. These are quite suitable for covering a wide flat area.
Depending on construction, the horizontal beamwidth is anywhere
between 90 and 150 degrees, with a vertical beamwidth of approximately
10 degrees. The idea is to send most of the RF toward the horizon,
and not into the air or into the ground. Gain varies from 8dBi to
perhaps 15dBi depending on type and construction.

Articles on the AMOS antenna design at:
<http://www.qsl.net/yu1aw/invertamos.pdf>
<http://www.qsl.net/yu1aw/amos_article.pdf>

AMOS and Franklin type antennas:
<http://pe2er.nl/wifisector/>
<http://yu1aw.ba-karlsruhe.de/ANT.htm>
<http://yu1aw.ba-karlsruhe.de/vhf_ant.htm>
<http://www.qsl.net/yu1aw/vhf_ant.htm>
<http://www.brest-wireless.net/gallery/AntenneAmos>
<http://www.brest-wireless.net/wiki/materiel:amos>

You'll find that there's much more to running a WISP (wireless
internet service provider) than antennas and radios. If you plan to
grow the business, you'll find that it's exactly the same as a wire
line ISP, except you have a basically unreliable method of delivery.
One leaky microwave oven will trash connectivity for a very wide area.
Like a wire line ISP, you'll need a backhaul, billing, support,
installation, service, and troubleshooting. The usual oversight is
that wire line ISP's don't make much money from connectivity. They
make their money with secondary services such as web hosting. If
customers bring their own equipment, you'll need some way to

troubleshoot *THEIR* problems and possibly charge for fixing *THEIR*
computer. You could supply the radio equipment to the customers which
will put you in the equipment leasing business. Plenty to think about
but the one that usually causes problems for startup WISP's is "who is
going to answer the phone when the customer calls to report an outage
at 2AM?" Start reading about the WISP business here:
<http://www.bbwexchange.com/wireless_internet_access/>
<http://www.bbwexchange.com/howto/>

Good luck.

Okay well the answer is relatively simple.

"Height is might". Antenna system should be as high as possible, clear of path obstructions and provide gain in the direction of interest. For equal coverage in all directions this generally means a vertical collinear design. The idea is to have a very small angle vertical pattern as close to horizontal as possible. (ie radiates most of its power to the horizon)

In my experience, end fed (ie at the bottom) collinear systems (especially home made ones) tend to have current imbalances in the elements such that the lower ones get slightly more than the upper ones. the result is that the pattern skews undesirably upwards at a slight angle. You also get less gain per unit length using systems that feed from one element to the next rather than (say) a number of dipoles fed directly in parallel. There is an optimum spacing between elements for best gain that is difficult to get in element to element systems.

Of course 2.4GHz antennas are harder to size accurately and test equipment can really drain the hip pocket!

If I was doing it for a community system I wouldnt bother doing antenna construction as such. I'd probably go and buy maybe 4 of a well known base design of moderate gain and stack them for gain. These may end up being in panels rather than simple verticals. Keep in mind though what you are trying to achieve and best bang for your buck. Doubling your antenna size gives best case an extra 3dB (often less) of gain. In a free space model the extra distance covered is double the distance for every 6 dB. This initially sounds good but once you are no longer line of sight, that gain is nothing compared to the losses. I dont know the 2.4GHz numbers off hand but the range numbers might be something like 5km, then 5.1km with an extra 6dB. Of course those users that have a signal already will get a slightly stronger one and thus may get a higher data rate but there will be a point where more gain and a different system design is better. Using multiple channels and WAP repeaters or bridges/links although likely bringing the bandwidth down will give you greater coverage albeit sometimes at the tradeoff of speed.

I dont have any modeling stuff for 2.4GHz networks as such. You tend to need a lot of obstructive rather than terrain data information. You can however take some photos and hand enter some near field terrain info to look like buildings. Have a look at "Radiomobile" as a prediction tool. As far as I remember it is GPL software that you will find other users have used for WiFi networks. You can see the effects of gain and height very easily and it will give you a lot of go/nogo help for particular areas you want to supply access from.

Apologies for the length!

Bob

Uh, resistance? Are you talking about DC resistance? What about impedence?

You also stated, "Unfortunatelly, the antenna was resonant on top band but with a very low resistance so I have to start all over again" after saying, "maximum gain comes about when resistance aproaches zero." Which is it? Is your low resistance good nor not?

I beg to differ, having established one (failed) WISP a few years ago.
The higher you place the antenna, the more interference from other
2.4GHz users you'll receive. The license free bands are really
polluted. Once you get high enough to get adequate coverage of the
client radios, any additional height is counterproductive as it only
increases interference pickup.

Clear of path obstructions is correct, but difficult to accomplish.
The most common screwup is insufficient Fresnel Zone clearance,
especially when it hits the ground. For example, let's pretend our
WISP is running out if his house to a similar client radio, both with
rooftop antennas. That would be about 7 meters off the ground.

Quiz: At 2.4GHz how far away can these they be before an 80% Fresnel
zone hits the ground?

Answer:
<http://www.terabeam.com/support/calculations/fresnel-zone.php>
Plugging in various ranges until I get a 7 meter Fresnel Zone radius,
I get about 2.5km range. Any further and the antenna at one (or both)
ends will need to be elevated.

>For
>equal coverage in all directions this generally means a vertical
>collinear design. The idea is to have a very small angle vertical
>pattern as close to horizontal as possible. (ie radiates most of its
>power to the horizon)

I again beg to differ. Vertical collinear antennas suck for WISP
service. Lots of problem. On omnis with sufficiently high gain, the
extremely narrow vertical radiation pattern, and the apparently
incurable uptllted pattern, results in sending the RF to various
useless directions. There are antennas with a few degrees of
downtilt, but my testing shows that they still have uptilt when
mounted on a tower outrigger.

In my never humble opinion, the proper antenna for WISP service is a
90 or 120 degree sector antenna. These offer a solution to the uptilt
problem in that they can be pointed downward without having most of
your RF go into the sky on the backside. See photo at:
<http://www.qsl.net/yu1aw/3InvAmosa7.JPG>
These are 3 antennas, connected to 3 different access points. However,
the 3 antennas could just as easily be run by a single access point,
by using a combiner/splitter, yielding plenty of gain with the
advantage of downtilt.

>In my experience, end fed (ie at the bottom) collinear systems
>(especially home made ones) tend to have current imbalances in the
>elements such that the lower ones get slightly more than the upper ones.

>directly in parallel. There is an optimum spacing between elements for
>best gain that is difficult to get in element to element systems.

Yep. However, it's not an "imbalance" that causes the problem. End
fed vertical collinear antennas belch half of the RF from the first
1/2 wave dipole near the connector. 1/4th or half of what's left
comes out next half wave section. 1/8 of the RF from the next section
and so on ad infinitum. what that means is that there's not much RF
left by the time the you get to the tip of the antenna. It's for this
reason that I like to mount my end fed omnis upside down on the tower
outrigger. This is often vetoed by the tower aesthetics committee but
when I get my way, it works very nicely.

Incidentally, the uptilt problem is mostly solved by some commercial
omni antennas with a center fed collinear dipole arrangement inside
the fiberglass tube. This is common at VHF/UHF frequencies but I
haven't seen it at 2.4GHz.

>Of course 2.4GHz antennas are harder to size accurately and test
>equipment can really drain the hip pocket!

Bah. The stuff costs money but there's no need to buy state of the
art hardware. A good RF sweep generator, direction coupler, diode
detector, general purpose oscilloscope, marker generator, and a mess
of coax cables, adapters, and terminators, are usually sufficient:
<http://802.11junk.com/jeffl/pics/home/slides/BL-shop5.html>
The HP8620A sweep generator is fine (but my 2-4GHz plug needs work).
There are two Wiltron 610D sweep generators behind the pile. I don't
recall what I paid for all the sweepers, but it wasn't huge.

The real key to sweeping the antenna is in the directional coupler or
VSWR bridge. Good ones are expensive and easy to destroy. So, build
your own for just 2.4Ghz:
<http://pe2er.nl/wifiswr/>

>If I was doing it for a community system I wouldnt bother doing antenna
>construction as such.

Maybe. Commercial sector antennas are somewhat expensive.
<http://www.superpass.com/2400-2483M.html>
It's a marginal proposition to build your own for just the base
stations. However, if I were supplying client radios for the
customers, I would certainly consider rolling my own to save a few
dollars per install.

>I dont know the

Using repeaters (range extenders) or mesh networks also has the
disadvantage of hogging air time. With a single channel store and
forward repeater, it takes twice the air time to move a single packet
between link endpoints. That's not a big deal in an isolated client,
but with a heavily used and high access point, it can easily be
considered a form of interference. Wireless is a shared medium. If
there are packets flying through the air because of repeaters, they
will reduce the available air time rather rapidly. Such repeaters
also have a lousy delivery success rate, resulting in retransmissions,
which reduce the available air time even more.

Speed is also an issue, but for a non-obvious reason. In such a
shared environment, you want each transmission to occupy as little air
time as possible. That means you have to send your data as fast as
possible. Signal strength and maximum speed are directly related (all
else being equal). The last thing you need is a customer stuck at the
minimum 1Mbit/sec and monopolizing a disproportionate amount of air
time. I setup mine to do 802.11g OFDM modes only and to ignore all
802.11b speeds. That gives me a 6Mbit/sec minimum OFDM speed, which
uses approx 6 times less air time than 1Mbit/sec. It also changed
having all the beacons and broadcasts from 1Mbit/sec to 6Mbits/sec.
When possible, I like to use fixed data rates, typically 12Mbits/sec
or more.

>I dont have any modeling stuff for 2.4GHz networks as such. You tend to

Yep. Great program. I use it often:
<http://www.cplus.org/rmw/english1.html>
However, it's only as good as the topographic data. Most commonly
available (for the US) are the SRTM v2 data at 1 arc second (30

meters). That's good enough for doing general topography (mountains and valleys) but not good enough for doing urban canyons and small neighborhood WLAN's. Data for the rest of the world varies by country, but most of it seems to be 10 times less resolution.

>Apologies for the length!

I won't apologize for my length. I'm partial to details and explanations over the all too common one-line quips and cute remarks devoid of any useful content.

You both missed the point. What are you going to do with 4 or 5 wireless routers stacked on top of a 8 port switch? I was talking about losses of cat6 vs. expensive infrastructure. I hope nobody was thinking that 1000' of hardline and connectors would be cheaper.

Really though, Jeff stated earlier that there is more to it than radios and antennas. We had a community WISP out here. About as much headache as running a cable company. If you are setting up for an IT show or if money is no object, no problem. If you are trying to make a little money, I hope there is a lot of dissatisfaction with the other ISPs in town. The one here got bought out by major players and everyone went away.

What does he mean by community? A small town? A campus? A truck stop? Unless it's a truck stop or food court, you will probably need a constellation of AP's and all the network and coverage optimizing and diagnostics to go with that.

Looking for advise here will probably give you a bigger headache What you need is 4 or 5 bright stars to build out and run it for you.

I had a hard time separating what he actually thought from what he was
complaining about.

I find that even if go to great pains to be extremely clear and eliminate
all distractions from a document, and write for a 6th grade reading level,
only 10% will actually get it. Some will cling to a word that has special
meaning to them and go on a wild tangent and some will only get 3 or 4 words
out of it, throw away the context and quote those words.

I feed antennas with a resistive feads without reactance, when it
becomes an impedance I retune or should I say the radio retunes
the antenna to make it resistive
to make it resistive

No, I don't think so. THE POINT is that the guy asked about particular antennas. NOT for my advise on his plans, his love life, his Taro Card reading, etc.

Now we are clear out here where you are advising him what is possible, what equipment he should use, etc. What might be impossible. What well be too expensive. That he might find he may have to make adjustments to his original plan/design, etc.

I simply assume he can either handle it, or find these things out on the way and have some interesting fun in solving the problems ...

I just don't see the same shoebox you do ...

No. I have difficulty in feeding near zero resistances. I opt to feed
high resistive loads without regard
to SWR I just do not want a reactive load for transmitting. For
receiving the low resistance or even impedance
really is of no concernl. When I design a antenna say for top band I
want the near zero resitive load point to be about
the low end of the broadcast band which allows for coverage of all the
top band but makes the 80 metre band centered around the zero mark!.
The beam that I am building is not aimed at small volume but of a 4
foot antenna of ultra lightness so I can use a a pan and tilt
mechanism as used with CCD cameras. By the way this particular antenna
is an attempt to make one continous lobe for 180 degrees of a narrow
width without nulls. If this is successfull I will then place a dish
reflector(probably about 3 to 6 ft diameter depending on weight)
behind it and call it a day for the winter.
I promised to make a antenna for somebody so this continual testing
game just has to come to a halt
Regards

Art
I understand your reluctance to move away from the term impedance but
I prefer to refer to resistance in the absence of reactance.

I feed antennas with a resistive feads without reactance, when it
becomes an impedance I retune or should I say the radio retunes
the antenna to make it resistive
to make it resistive

OK Art. I hate to put it this way, but you really need to take a course or
two to get on the same page and be understood in these subjects. Even a few
nights with the ARRL Handbook may help bridge the gap.

For instance. With Lumped Constants, when inductive reactance and
capacitive reactance are equal, the circuit is in resonance. Any series
resistance in the circuit will become a significant load and result in loss.
In an antenna, there will be a characteristic impedance of the feed point.
Although it may include the loss resistance, other factors determine that
impedance. Since there are nodes of high and low impedance on the antenna,
the feed point may be modified or relocated for different impedance. Also

because of the nodes, there will be high and low currents along the antenna. Where the current is high, the losses in the resistance will be greater and most greatly affect the Q.

I do not have any lumped constants. Maxwell's laws do not include
lumped loads only
distributed loads and my antennas revolve solely around the laws of
Maxwell which
being based on equilibrium includes all four forces of the standard
model
I have no problem with your suggestion, it is that I am just to busy
at what I do.
True ,you can feed at any point but there are penalties with that
aproach which I don't want to mess with,
I prefer to have continual tuning or adjustment at the antenna. Just a
reminder but my design is not
focussed around a planar form that concentrates on inter coupling of
radiators .
Best regards no offence taken

Art:
Of course you have lumped elements in your "antenna". You have
a shoebox full of wire, fashoned into contra-wound coils. Also, the
tuning device you described is a variometer, again replete with COILS.
These coils constitute "lumped constants", as you call them.
Mistakes like this show that your equilibrium is tilted.

>
>Cat vs. WiFi?

Sure. We had a neighborhood LAN/WLAN for many years. It started out
as a neighborhood bootleg satellite TV and CATV distribution system in
the 1970's. Over the years, conduit, fiber, RG-6/u, CAT5, and
wireless were added. It does some TV, internet, VoIP, bungler alarm,
intercom, neighborhood watch, surveillance, and gaming[1]. I built
most of it myself. At it's height, we had about 15 houses wired into
the system (all sharing one DSL line). Health issues and general
laziness are limiting my ability and time to do installs, repairs,
troubleshooting, and cable chewing squirrel abatement. The price and
availability of DSL and cable had made it easy for individual owners
to get their own services. Due to the dense Redwood, Oak, and Douglas
Fir forest, wireless was rather problematic between some houses. So,
I resorted to horizontal drilling under the road, conduit, and lots of
scrap CAT5. There was no problem running 900ft between switched ports
as long as I kept the line protocol to 10baseT HDX.

The roll of CAT6 I previously mentioned is for rewiring a clients
office for all gigabit ethernet. Pricewise, is still cheaper than
fiber at gigabit rates.

>Isn't that kinda like comparing a hardwired phone with a cell? One I
>can do without, the other I can't ...

Maybe. The CTIA notes that 15% or more of cell phone use the cell
phone as their sole means of voice communications. (That's wrong
because they only consider if they do NOT also have a conventional
POTS line and ignore VoIP over broadband). Still, it's a growing
number that have elected to consider cellular as essential. Like all
analogies, the wired versus wi-fi will fall apart if you dig deep
enough. Still, there are sufficient similarities in function where
they can be considered alternatives.

I have a customer with a mostly wireless office. Everything from
desktop to 4 line phones are wireless. That's because the ancient
Victorian nightmare of a building they're in has no place to run CAT5

except the OUTSIDE of the building:
<http://802.11junk.com/jeffl/pics/drivel/slides/SCZ%20Victorian%20wiring%20mess.html>
The cost of running surface conduit either inside or outside was
prohibitive, so they went wireless.

I'm drifting off topic here, so let me get back to the original
"community" network. Running copper or fiber is an option if the
community is small enough, the local authorities are cooperative, and
density is high enough to avoid long runs. It's been done in small
towns and planned communities many times. It's far more cost
effective than wireless, mostly because wireless does not scale very
well. The same high density systems that work so well with wired
networking, cause interference and capacity issues with wireless. On
the negative side, copper has become so valuable, that running it in
3rd world countries has become a futile exercise. It will be stolen
as soon as it's installed. That's one reason that wireless phone
penetration in 3rd world countries tends to be very high, the
alternatives just don't work.

There's lots more to wired versus wireless, but this is not the time
or place to discuss them. If the "community" is huge, and copper is
not an alternative, then use Wi-Max, not Wi-Fi. If the community is
like my miniature neighborhood LAN/WLAN, use whatever his handy
including Wi-Fi.

[1] Just before its demise, my biggest problem was a bumper crop of
12-14 year olds, turning the system into a big chat room and gaming
network.

I think a 10 year old level is more appropriate. It's roughly what TV
shows try to target.

Topic drift is a problem, but boilplate solutons are what drive the
technical newgroups and mailing lists. Whenever someone asks a
question, the vocal experts are usually first to misinterpret the
question and provide their favorite boilerplate answer. In my case,
it doesn't matter what antenna problem you're having, a computer model
will provide the answer. Lots of other approaches (careful
measurement, ignore VSWR and use a field strength meter, etc) that
vary with the person providing the analysis and boilerplate. OF
course, the answer never completely solves the original problem, so
the discussion drifts off into optimizing the computer model, instead
of fixing the antenna problem. My guess is about 3 back and forth
postings and the original topic is lost. Kinda like this posting.

Anyway, I've never used or built a G5RV, know nothing about the
antenna type, and propose building a computer model of the antenna,
supporting structure, and nearby buildings, that will solve any
problem with a G5RV, including operating it on bands for which it was
never designed.

I merely used Lumped Constants as an example to describe the relationship between Inductive and Capacitive reactance, resistance, then to go on and show how it is differently applied to antennas and impedance. Where to feed it is exactly the point in providing a transition between the feedline and antenna. For example: Lumped Constants in an antenna tuner not only adjust reactance by providing the conjugate reactance to whatever is presented at its input terminals, but also adjusts impedance, akin to adjusting where the current minima and maxima will be in relation to the tuner's output terminals. There are a great many ways to physically do that, either by linear loading, lumped constants, transmission lines, transitions, transformers. Look into the feed methods used for Yagis.

David I have used Yagi's for decades. Nothing wrong with them, they
harfest more than 90%
of radiation available and are directive and very easy to make. What I
am pursueing is a different aproach to radiation
in an effort to make smaller and efficient antennas without resorting
to fractional wavelength.
It should not matter to you if I succeed or not. We have had many
years of the Yagi without much improvement so I am turning antennas on
its head
and starting again from where the Masters put their ideas together.
Maxwell just played with numbers and equations supplied to him by the
forerunners
he just wasn't interested in equilibrium he was interested in the
interplay of numbers only. It is our good luck that all the
forerunners included the consequences of equilibrium in all their
functions so whether Maxwell was interested or not the equilibrium
format was included whether he understood that or not. Now you and
everybody else knows that computor programs were built solely around
Maxwells laws with the condition of equilibrium. Whether you like it
or not the program had to be extended so it was of use to amateurs who
used intercoupling of elements as a short cut to approximations of
radiation which foirtunatelly are quite good such that we have become
lazy in poursueing the laws of the Universe on the assumption that
there is no such
thing as a Universal law. I believe there is a universal law and I
will not be detered from that search from the likes of you who
apparently solved all the laws of nature before I started. If nyou got
there then so can I

Have a happy week end and for goodness sake quit the drinking and
savore the World as it is
Regards

That's what Galvani said about the frog's leg. Republicans merely polished the science of that jerk-reflex and both sides of the same party are tugging hard on our wallet - not just touching. And in the middle of it all, McCain sat through the crisis meeting like he had suffered a brain aneurysm.

At least he got to nominate his own night-nurse to change the silver drool cup this evening. Our first presidential candidate on life-support.... Sara Jane may try an experiment with silver and copper forks on him to get him to twitch for the cameras - if she can find any nerve, that is.

Mike I am not a total newby to antennas. I understand them in my own
way very well.I obviously have a problem in communication

I am changing the dimensional structure purely to get the anti
resonant point at the center of the top band instead of the standard
resonant point
which is too low to realistically to use. Now the antiresonant point
will be between 100 and 200 ohms resistive which allows me to feed it
directly from a 50 ohm transmission line (3/4 andrews) with negligable
losses as the mismatch is resistive. Past work and experimental
results lead me to belive I have a beam for top band with approx 9/10
dbi gain when a reflector is not used. Now who in the World would
throw away the thought of such a antenna because
of the silly aproach of old timers who consider all is known otherwise
they would have changed things a long while ago? The design with all
info will eventually appear on my page. Up to now I have tried to
share everything but old timers on retirement close their minds and
cannot abide change.
If I see from past postings that a dialog could be rewarding I will
respond but they are few and far between. There has not been one
person on this newsgroup over the last few years who is able to look
at a Gaussian field with an applied time varient field and a radiator
and mathematically prove that the results are the same as Maxwell.
True the units are different between Gauss and Maxwell but to deny the
mathematical equivalence without doing the math is unconciousable

Art -

An antenna with an input impedance of 150 + j 0 ohms has a reflection coefficient of 0.5 (50%), a return loss of 6.02 dB, and an SWR of 3:1 to a 50 ohm source. Probably not many transmitters would be happy with that magnitude of load mismatch.

Do you maintain that the losses defined by these parameters are negligible to amateur radio operators?

Not when you are in the experimental mode. My output are tubular
and while I am experimenting I am loath to add a transformer.
Must admit I am very surprized at the losses you calculated.
I would have thought it have been about half of that but then I should
have looked it up
instead of relying on the 3/4 andrews keeping things down. For
recording the resistance and capacitance
over a few megerhertz I aam comfortable with what I am doing since
things will change when I take it off the 50 gallon plastic drum.

David
If a radiator is ferromagnetic it will still create eddy currents but
on a smaller scale than with diamagnetic material as well as the
material being lossier because of the hysteresis. The bottom line is
that the eddy current becomes swamped by the initiating current and
the same goes for the magnetic fields.
Keep the above in mind and then review a tank circuit to see the
implications of the above, I am sure you will be surprised if you are
familiar with the
attributes that a tank circuit has beyond the slosh back and forth.
You should look up wilkpedia for aluminum scrap metal sorting to see
the different
projection angles (levitation) of the different materials being
sorted into the separate containers. Move beyond non magnetic
stainless steel and the elevation angles change very quickly. As far
as neutrinuos goes you would have to look very hard for a material
that would absorb a non bound free electron I believe it is less than
5% of the materials on Earth that would interfere with the placement
of a free electron which would put it somewhere below 1/2% in termns
of volume. Remember the less the ratio of eddy current the less force
available for spin which would cut out all DXing. Put that bottle down
and get that brain of yours back in order. Why not watch the debate
with a cup of hot tea?

Has anyone given thought to converting attic "techshield" insulation
to a HDTV suitable antenna? I have a roof dormer (vertical section)
that faces the desired reception direction.

I am thinking a UHF patch antenna and a VHF patch antenna and then
combining the two - traditionally.

Ideas?

No, you didn't say 'per' anything. The word 'Inflation,' without any qualifiers, implies 'per year.' Per your lifetime is an ambiguous reference and more so since apparently you're not dead yet.

A popular antennas over here in the UK is a centre fed doublet,
80 to 100 Foot top with 450 ladder line feeder into your ATU. You
will need a balun near the shack end if your ATU is coax only input.
This makes feeder access into the shack easier than balanced feeder
coming in. DX Engineering makes excellent baluns for this purpose.
This antenna will work all HF bands, 80m and up.

At the moment I have an 80m inverted V dipole and a 40 metre one fed
with the same RG213 coax (about 60 feet of the stuff). These antennas
work worldwide DX very nicely, even though the apex is only up at 32
feet. NO atu needed :-)./ However I'm shortly going to erect the
doublet described abovce so that I can work all the WARC bands as
well. I already have a 3 el beam for 10/15/20m.

Yes, I've used the stuff for patch antennas at 2.4GHz. It has a very convenient aluminum foil layer on both sides. It works fairly well with various foam dielectrics being useful well into the microwave region. I'm still not sure of the electrical characteristics of the varous insulating foam boards. I did best (so far) using common Styrofoam, glue, and aluminum foil. Also common stationary store sign board material. Lots of foam board types out there:
<http://www.rigidfoammachining.com/rigid-foams.html>
The hard part is figuring out which type of foam your favorite insulation uses and what the manufactory has added. I found one brand that has some kind of anti-static conductive additive added to prevent the foam board from turning into a big capacitor and zapping the installer. Kinda marginal for an antenna. Be careful and do some measuring.

However, you're not going to do well with HDTV and patch antennas. Unless you're building a single channel TV antenna, the patch antenna is just too narrow band to be useful. It's also difficult to build complex structures on home insulating foam. The patch size will be rather huge to cover the lower VHF frequencies.

Good idea for a fairly narrow band patch antenna, but HDTV is the wrong application.

In fact the losses are very low. 1000 ft of 7/8 hardline at 1.9 MHz has a total loss of 0.68 db when terminated in 150 ohms. The total loss includes 0.26 db due to a the VSWR load of 3:1. Data from: "TLW, Transmission Line Program for Windows", version 2.02.

Feed line losses maybe, but total system loss will probably be
overwhelming.
Or at least to someone like me who likes to actually radiate most of
the
power I feed to an antenna.
The feed losses feeding a dummy load at 1.8 mhz are likely to be
quite
low also. Doesn't mean I would want to use it as an antenna though.
In one of his posts, he even goes as far as to claim appx 9 dbi gain

from his very small vs wavelength device.
This is appx equal to the gain of a FULL SIZE 3 element NBS yagi.
The only thing I keep observing here is a full load of horse hockey
that keeps emanating from a certain delirious old fart now living in
Illinois.
9dbi gain on 160m with a radiator the size of two shoe boxes,
consisting
of loads of wound 22 gauge wire. I don't know how many feet, but
probably in the hundreds anyway.. Can we spell some serious loss?
In some posts he seems to infer that he is now winding it on some
plastic barrel or garbage can, but I wouldn't expect a drastic
increase
in performance, considering the frequency being used.
I won't mention that in other breaths he takes, he claims no real
gain, but basically an omnidirectional antenna.
The wind changes direction depending who he wants to listen.
This is some good stuff. The comedy channel is missing the boat.
Heck, the feeder losses are really not much of an issue being
at 1.8 mhz, the loss of most any decent coax is very low.
Nearly ladder line performance.. You could be 10/1 SWR and
it wouldn't kill you as long as the radio didn't shut down.
In his case, the coax probably radiates more than the antenna. :(
His antenna is not a whole lot different than someone using an
Isotron. And in the case of that small antenna, it's not unusual for
the coax cable to do a good bulk of the actual radiating.
At least the people that make the Isotron have the common
decency not to proclaim some miraculous discovery of science,
and/or claim 9 dbi gain from their dinky antenna on 1.8 mhz.
So I don't heckle them like I do Art.
If Art did likewise, he'd never hear a peep out of me.
But we all know Art is not going to follow that plan... :/

Not if the term in question has a widely accepted definition within the
field of its common use, in this case economics and banking, where the
widely agreed time period for specifying 'inflation' in percent is one year.

I don't believe that to b e strictly true. When we were on the gold
standard it was kept pretty level.
When we went off the gold standard gold shot up over night but I do
not believe the price of gold
has shot shot up a lot since then. I suspect copper was a better deal
at least up to a few days ago

Silver is difficult to purchase at this point ...

A few days ago, there was not an oz. to be had, which anyone wished to part with ... indeed, a friend of mine in the markets claims the middle east has sucked up great quantities, and quietly, recently ...

I have 281 of these in a small safe, I was not aware of that ... I will
have to look at that, got a link/URL?

I just took it for granted you could trust the govt. on such a serious
promissory note ("Silver IOU"), broken promises do not instill trust and
respect. I suppose the gold notes are just as worthless then?

But then, for some reason, such is not as shocking as it would have been
a few decades ago ... :-(

Feedline loss is what I was considering. As for the ultra
compact antenna losses are likely to be very high. The

problem with such structures is that they are impossible
to model accurately with any NEC based program.

Unless it is for the collector value, the silver certificates have not been
backed by silver for a very long time. Not sure of the date, but probably
20 or 30 years or more ago.

How do you suspect that when a $1 silver certificates was exchangeable
for $1 worth of silver?

Unless you did the exchange a REALLY long time ago, the transaction
is break even.

I think he was simply pointing out that something still backs the
"worth" of a "silver certificate" (well, if it still existed, in reality.)

Since our currently issued dollar has nothing behind it than our
production, possibility of producing, and labor ... and with a
frightening amount of that having "gone over seas", it is virtually
worthless ...

However, no one realizes this, well, seems to realize this.

Or, to summarize this:

The dollar is worthless and only those who have replaced these with real
objects/matter of value have any real wealth.

Indeed, money has become a religion, only those who can make a leap of
faith as to it having real worth are believers ... at least here in the USA.

The "worth" of any medium of exchange is whatever the "worth" is
perceived to be, whether it be cash, checks, certificates of deposit,
stock certificates, money orders, bonds, gold bars, silver bars, or
shiny beads.

About the only medium of exchange that had any intrinsic value was salt.

The "value" of real objects is also whatever it is perceived to be; I
don't think my house is worth $500,000, but the housing market does.

Look up supply and demand and then tell me why diamonds are so "valuable"
and why no one is paid in salt anymore.

None of this is unique to the US, it is the way the economy works in
the modern world.

Frank & Art -

Note that my post upon which you both commented was based on a SYSTEM evaluation, and was not restricted to the performance of a coaxial cable having a given mismatch condition, used between the transmitter output terminals and the antenna input terminals.

Also note that few, if any, transmitters can safely deliver their rated r-f output power into a load SWR of 3:!.

This is true no matter what is the power rating of the transmission line type used in an antenna SYSTEM with a 3:1 SWR.

RF

Modelling suggests that the efficiency of such an antenna degrades quickly
for dipole lengths less than about 35% of a wavelength.

80' is 28% of a wavelength at 3.5MHz.

Here's a chart of gold prices since 1975.

http://www.kitco.com/scripts/hist_charts/yearly_graphs.plx

Seems to me it "shot up" from '76-'79 and '05-'08. I rolled
my IRA over into gold because of the Y2K scare. :-)

Walter Maxwell agrees. In "Reflections", he suggests the
minimum length for a dipole should be 3/8WL.

In the portion of my post, top, what didn't you understand?

Diamonds, valuable? Are you truly an idiot man? As I have pointed out,
in the past, diamonds are worth about $5 bucks a carrot; now, that is
still a bit expensive to pave your driveway with, but none the less
worthless when compared to what people (like you) THINK they are worth.

See the following and wakeup!:
http://www.wired.com/wired/archive/11.09/diamond.html
http://www.apollodiamond.com/
http://www.gemesis.com/

Diamonds are what the next wafers of microprocessors and chips will be
built on ... without a doubt, they will be cheaper in the future than
they are today, but still worthless, virtually ...

And yes, like I have pointed out, idiots who think the dollar is worth a
dollar abound! And, just ignore them starting up the presses and
printing worthless dollars ... I just wish I had a press and was allowed
such freedom! ROFLOL

I was trying to point out that you can no longer go the the bank or whatever and exchange your paper silver certificiate for silver backed by the government.

YOu are correct , paper or other objects that have no use are only worth what others will pay. I have read of used stamps going for atleast a million dollars. They are of no use at all that I can think of, but to a collector as there are only one or two known to exist that one is worth whatever you can get for it, nothing to millions.

He also stated he would possibly be putting a 6 foot or so dish behind
his antenna to add gain. Wonder at what frequency he expects that to
work? I think it was in the 80m or 40m range. Hmm.

Let me expound upon all this ...

If you pay $5,000-$10,000, or-more for a diamond, then you go to sell the diamond--would you expect to get close to what you paid?

Do you realize in such places as china they are using this technology and injecting "flaws" (purposeful ones to hide the fact they are man-made) into the diamonds, and they are as-good-as-natural? Duh, this means the market will eventually be flooded with this stuff as "cheap as sand!"

Only a fool would invest in diamonds, if you have 'em, dump 'em before EVERYONE finds out! And, remember, you heard it here first--if you feel generous, ship me a 10% "consultation fee." ROFLOL

The only good use for diamonds are industrial ones, anyway ...

Unless you are in the business, you will be buying at retail prices
and selling at wholesale prices, just like anything else.

Send me all your gem quality, 2 carat and up, certified, blue diamonds
and I'll pay you $10 a carat.

For carrots, I'm only willing to go $0.29/lb.

You are probably correct concerning a 3:1 SWR. Transmitters
usually have to meet full output into a 2:1 SWR, all phases, with no
sign of oscillation. In this case I had assumed that a matching network
would be used between the PA and coaxial input.

And, let me expound upon this to the point of rationality ...

Take a court punishment, enacted under the law, as defined by our forefathers ... under fair and just/unjust doctrine ...

A transient, a poor person, etc, they would be meted out a $10 dollar fine, a worker--perhaps a $50 dollar fine? A doctor--perhaps a $100 dollar fine? Bill Gates--perhaps a $100,000 dollar fine?

You get my drift? It is fairness, trust, respect, etc. which has vanished ... and with it, a fairness in our financial institution(s) ...

It is why respect for the system is either gone, or will be in the near future. Do you really want to live in a world like that? Would in not be sane to take control of our "public servants", before we suffer?

That is too simple, you are honestly confused ... let me go into great detail ...

DO NOT be a MOTIVATED BUYER ... DO NOT GO AFTER WHAT THE MARKET IS HOT AT ... etc., etc.

Or, to summarize, DON'T GO TO THE GROCERY STORE WHEN YOU ARE HUNGRY ... go before, contemplating your future needs ...

But when you don't need it, go for fun. Go and find "one" ready to haggle, a MOTIVATED SELLER!

My gawd man, who instructed you on the art of capitalism?

Regards,
JS

I have one patch antenna. I made it from online plans for 1.58 GHz -- a GPS antenna for my old Garmin handheld. With a short length of coax attached, I secure the patch antenna to the luggage rack and not worry whether the Garmin is near a window. (Newer units are more sensitive -- no need.)

The patch antenna is not very directional, a good thing for GPS, since you want a view of the whole sky but maybe not such a good thing for TV reception unless you want a non-directional antenna. I think the patch antenna is circular polarized. You'll lose 3 dB using it for linear polarization.

Sure, it might work for UHF TV but it doesn't seem like the ideal.

And we wonder why usenet is being dropped by one ISP after another? It is behavior such as this that keeps folks away in sufficient numbers as to not make usenet worth the expense.

Nothing stinks more than pissing contests. Only a moron would be amused by this juvenile banter and they don't have a clue as to how to access usenet, or what it was for, when it was available.

I have one of these. I can hit a repeater over 10 miles away on 6
Meters, using a 5 Watt HT and 100' of RG-58.

If you put a FSM out and start fiddling, you find that some radios don't do their best above 1.5:1 and many start shutting back past 2:1 and the internal tuners are only spec'd at being able to match 3:1 or better. Even after that, there is sufficient loss, that your 100 watt radio is now an 80 watt radio. It may be a neat portable feature, but since you have to get the antenna down below 3:1 anyway. Might just as well do it right from the beginning or at least get a big tuner. We didn't worry about these things with the Pi-net tuning.

There are several discones out there by Diamond, Icom and others. Do work fine 1.2 and VHF/UHF and everything in between too. Good to have for the first outside antenna. There are gain omnis and yagis out there too. Best to use the best coax you can get, even hardline if you can afford the connectors. If you can keep the length down to 30' or less you will be way

ahead.

They are comparable. CommScope, Inc. wbc400
Yours may be a little more flexible. Same size, connector, loss per foot,
material.
like Times lmr400
like Andrew cnt400
Quality? You be the judge, you don't get the cool Andrew logo.

It seems that CommScope bought or merged with Andrew:
http://www.commscope.com/andrew/eng/solutions/wiress_infra/

Make sure it never gets water inside. Use a RG213 pigtail around the rotor.

JB
Things are gettung side tracked here. When I am experimenting I
measure capacitance, inductance
and resistance against frequency where the totally resistive ponts are
of interest.
The standard resonant points will be low resistance and the
anti resonance points can range from 50 ohms to 300 ohms and I plot
these against frequency,.
So a poster took issue with the 300 oghms with the suggestion that I
advocated the use of 300 ohms
connected to 50 ohms for transmission. That was a comment to bait and
people started to bite at it
especially when it was mentioned that 3/4 of the power would be lost.

When all the data is compiled it then becomes useful
with respect to antenna design. For measuring purposes it is only
important that the anti resonant pont is resistive since there are so
many factors that
t
can change the ohmic value in its final environment. It is then that
you become concerned about the matching
The poster mentioned a" system "in his evaluation which has no
relavence to the project at hand, he only posted
for baiting purposes and frankly his supplied figures was just a hoax
or just a plain error that had no connection
to the post I made.
Art

How are you determining the resistance values of a theoretical antenna? Are you using known resistance of various materials and assuming various resistive losses?

Or are you using resistive terminations?

You DID NOT read the article by Wired, I can tell ... NO, these "manufactured diamonds" cannot be told apart from those occurring in nature, by ANY JEWELER ... other than they SHOULD bear a laser engraved number upon them.

To tell the difference, they must be placed under an electron microscope ... and the only "difference" that will be seen is that THEY ARE TOO PERFECT--ABSOLUTELY NO FLAWS, THAT IS IT! GET IT RIGHT--THEY ARE REAL!

China is creating them complete--no laser mark and with FLAWS ... place 'em under an electron microscope and you can't tell the difference. The reason?, duh, they ARE REAL. (anyway, just buy a BIG manufactured one and have it cut down to remove the mark--however, it will still be more perfect than any found in nature)

Exceed the cost of mining the "natural ones?" Naaa, you can't even mine 'em at $5 bucks a carrot ...

I repeat, only a fool would buy a natural diamond ... you can find the manufactured ones in better jewelery stores ... they are about 1/3 of the cost of natural ones, at this time ... however, I just negotiated the price to ~%25 ... however, I still got burned, the wife just had to have it though. :-(

Actually, there are material harder than diamond ... this makes diamond,
actually, less appealing for even industrial uses:

http://24carat.co.uk/harderthandiamondframe.html

Making your question even more valid, i.e. the part, "Sure, but what has
that to do with buying stuff from the store?" So, consider it answered!

Regards,
JS

Even cheaper, you can make your own diamonds in your microwave oven:
<http://hypography.com/forums/chemistry/804-make-diamond-out-of-your-microwave.html>
The main ingredients are charcoal briquettes and peanut butter.
Hmmm... they seem to have left out the requisite plama torch.
Let us know how the diamond smells, err... looks.

Oops, sorry for the double posting. Anti resonance for a free
space dipole is typically in the range of 7000 ohms. The
MFJ 259 is only accurate over a limited range of 5 - 500 ohms
so any measurements of anti-resonance is highly questionable.

Yeah, I do ...

Cut power to 25% and the other guy will see (if his s-meter is accurate)
a drop to half the reading ... at 80% power, little difference, other
than if you were just above noise floor in the first place ... however,
"tweaking" an antenna to perfect match/design criteria has always proved
to we worth the effort ... and especially to my ears--but my s-meter
also ...

According to:
http://ham.srsab.se/ww/temp/test_MFJ269.pdf
ARRL lab measures the range of the MFJ 269 is 6 to 400
ohms. Not sure what the difference is between this and
the MFJ 259.

Actually, I will go out on a limb over this point.

I have always found that a mis-matched, or "out of specs", antenna will continue to "ring the ether" a bit more efficiently than it will "pluck a signal from the ether."

I have simply grown to accept this from actual hands-on experience ... your mileage may vary ... and, of course, a poor antenna will continue to be poor even when perfectly matched and within original design specs.

The results you are measuring are certainly within the range of the
MFJ 259. As an example: a 493 ft dipole, 50 ft above an average
ground shows anti-resonance, at 1.9 MHz, and is 15,000 ohms.

Frank

I think you mean guess-meter:
<http://www.seed-solutions.com/gregordy/Amateur%20Radio/Experimentation/SMeterBlues.htm>
S-meters are notoriously inaccurate.

We have an Icom PCR-1000 remote receiver setup on a local mountain top
run by HRD (Ham Radio Deluxe) software. It's quite handy for tuning
and adjusting antennas and generating a polar plot for HF yagi's and
quad's. There are substantial site errors in doing it this way, but
it's still better than a field stength meter, or the traditional
"how's my signal" report.

I designed the 150w PEP power amplifier section for the Intech M3600
HF marine radio. Using VMOS xsistors, I was able to demonstrate
unconditional stability, at rated power, with any non-resonant load up
to about 8:1 VSWR. Above that the current went up a bit too high for
the 12 ohm load, and Vce climbed for the 400 ohm load. I might have
done better but didn't want to destroy the test radio. The radio was
specified to operate up to a 2:1 VSWR at full power and would reduce
power when the threshold reflected power was detected. Although I
demonstrated that it was possible to operate quite nicely up to 8:1
VSWR, without power reduction, nobody wanted to add that to the data
sheet for fear that someone would actually use it that way.

My guess(tm) is that most modern HF radios can also safely operate
into high VSWR loads, but suspect that manufacturers are also hesitant
to guarantee such operation. Most manufacturers don't even specify a
maximum VSWR and simply reduce power if excessive reverse power
(usually 2:1 at full power) is detected.

Disclaimer: If you trash your radio trying this without monitoring
the Pout, PA temperature, PA xsistor voltage/current, and checking for
oscillations on a spectrum analyzer, don't blame me.

Indeed, the 1-9 Signal Strength system was in operation
before S-meters were in standard use, dating back to the
very early 20th century. The "x dB over S9" came later.

Even when I got my first ham license in the early 50's,
the RF gain control used for CW rendered the S-meter
reading invalid.

That reminds me on how i advised coworkers on test taking strategy for
the PE exam. Don't waste time on areas that you know well, nor in
areas where you are really weak. Study the areas that you kind of
know. That is the best chance to improve your score. It works by
track record.

Concur.
RX level can be even more noticeable on high Q antennas off-resonance as you would expect.

Now add the line loss. Also, reflections don't seem to matter much with CW and SSB but can have an effect on some digital modes and certainly television.

With solid state PAs, not all are created equal, and shutback often errs on the side of keeping warranty costs down. Stability is in the reach of most modern ones now. The current can be dealt with if you can get the heat out of the junction to a point. But the voltage rise is the killer.

Also be aware that any transmission line will be significant in your measurements at the rig end.

The MFJ can see anti-resonance if it doesn't get confused on other oddities such as coax length or connector humps, reflections. It can get pretty dicey when you sweep because all these things jump out at you when the load is out of resonance and or mismatches anywhere on the line. Not to mention the harmonics in the unit when you are looking at high impedances.

It would seem the Andrew part # was dropped because of the duplication, or
one was a rebrand of the other. A quick google will turn up specs for both.
The wbc is spec'd ever so slightly better at 900 but may have just been from
rounding. I haven't bought either lately. You have the cable in hand
though, let me know if it meets it's own specs in testing. Have you used
either before? There are good reasons for choosing the right cable for the
job.

Yech. 19.5dBi maximum gain from a 0.6 meter dish at 2.4GHz. Most
such construction efforts end up with about 12-14dBi:

That sounds right..

I have two HF radios, (Kenwood TS-120, TS-870) and I often observe the
forward power climbing as I manually tune and reduce the reflected power.
At first glance, this would seem to indicate the rig had previously
throttled back its output in response to the consequences of a mismatch.

I never intentionally tune at anything more than a few watts, so perhaps the
protection circuits operate at less than full power, too. The autotuner in
the TS-870 uses about 10 watts.

This is normal operation not necessarily associated with
foldback. As the tuner is tuned closer to a Z0-match,
more and more reflected power is redistributed back
toward the antenna. Although not often done, one could
conceivably tune the system by monitoring the forward
power on the antenna side of the tuner and tuning for
a maximum. It's a conservation of energy thing. Maximum
forward power to the antenna = minimum reflected power
toward the source. Who says the tuner has no effect at
the antenna?

Hello All

Well after all the comments made and doing some research on the G5RV(I guess it has it place) I have decide to try something new and hopefully better.Here it is, the Mystery Antenna,I had all the parts at home, so it did not cost any money at this point.
Built it last night took about 1.5 hrs to build,including making my own center insulators and end insulators.Here is the link to the site,I am sure allot of you in this group know about it and looking forward to your comments.Will let you all know how it works,and some of the readings I get from it.
http://w5gi.com/mysteryantenna.htm

thanx all

I built a Mystery Antenna a few years ago just to see how it performed. Since then, John has changed his explanation a bit, but it is supposed to have a better pattern for its designed frequency, ala 20m, than the g5rv. Of course you can design it for whatever frequency you wish. I use mine for an all band portable antenna and it seems to work well.

I ended the parallel line in a pl-259. To that I attach, with a barrel connector, a ferrite bead balun (W2DU style) and then the coax to the tuner to prevent any common mode from coming back down the line. We use it at ham field day each year for the GOTA area.

I will not claim any particular advantage over, say, a dipole fed with ladder line to a tuner and will not quote reports, which are at best nebulus anyway, but it was fun to build and does work fine.

Incidentally, the cw operator at field day put together the D3 (the 1.5 wavelength ant) on John's W5GI site, tuned for the 40m cw freqs and it worked very well. Of course that requires a bit more real estate.

That's normal. You're not measuring forward power. You're measuring
RF voltage near the radio antenna connector. Once the load (coax +
antenna) moves away from a 50 ohm resistive load, all bets are off as
to what the voltage means. The same for a VSWR meter or watt meter
installed between the radio and the coax cable to the antenna. Once
the load gets away from 50 ohms, the voltage readings are not an
indication of power.

>I never intentionally tune at anything more than a few watts, so perhaps the
>protection circuits operate at less than full power, too. The autotuner in
>the TS-870 uses about 10 watts.

Yep. That's the way it should be done. The auto-tuners intentionally
reduce power to prevent damage if they cross through some odd
resonance that causes the voltage across some internal component to go
sky high. Half the power, 1/4th the voltage. It could zap the tuner,
but also zap the power amplfier if tuned at full power.

That begs the question "What happens to a transmitter if one
intentionally runs it with a high VSWR?" I don't know the full
answer. Conventional wisdom is that the xmitter finals overheat. I've
never seen much of that except with a tube power amplifier. With the
power amps I worked on, the voltage across the transistor would either
increase dramatically, or the current through the transistor would
increase dramatically. Excess voltage would zap the junction. Excess
current might cause overheating, but more commonly, would simply turn
the xsistor wire bonds into fuses or melt the junction even before the
heat sink could extract the heat.

It's not an indication of *NET* power but it is certainly an
indication of forward power (or reverse power). If it weren't
anyone could sue Bird for false advertising.

A high VSWR can cause over-voltage or over-current conditions
depending upon phase. Over-current conditions can indeed cause
the finals to overheat. Over-voltage conditions can cause punch-
through of the finals. The key to understanding the effect of
SWR on the finals is in understanding constructive and destructive
interference.

Have you ever actually measured the loss in coax adapters? See:
<http://802.11junk.com/jeffl/antennas/connector-loss/>
This was a bench test of a mess of adapters at 2.4GHz and 450MHz. The
numbers worked out to about 0.05dB loss per adapter at 2.4Ghz or
roughly what an equivalent length of LMR-400 would lose. At 450MHz,
the entire string only lost 0.2dB. I've also run the same test in
front of various radio clubs with perhaps 5ft of assorted adapters in
series at 450MHz. (sorry, no photos). The loss was also minimal.

However, I cheated. Not one of the adapters in my test had a "UHF
connector" at either end. When I ran the same test with a string of
UHF connectors, the results were far worse for loss and VSWR at
2.4GHz. For this reason, you're probably justified in replacing the
UHF connectors with N but not because of the added adapters.

Bird is very specific that their 50 ohm wattmeters are only useful in
a 50 ohm system. Here's one of your articles explaining how it works
in a 75 ohm system:
<http://groups.google.com/group/rec.radio.amateur.antenna/msg/717e8daabed08fd9>
Incidentally, I've been running cheap 75 ohm coax in 50 ohm systems
for years without any problem. Max VSWR= 1.5:1
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>
It's especially useful at 2.4Ghz, where the rather high coax cable
losses almost totally eliminates any detectable reflected power.

Agreed. I didn't want to go into the mechanism for where the excess
voltage or current came from, just the risks involved in tuning at
full power. You can run a radio at full power with a high VSWR load,
but it's likely that either the PA voltage or the current are going to
approach the point of no return. Reducing power is much safer than
finding the limit the hard way.

My own experience with a TS-2000 strongly suggests that this radio
does reduce its transmit power into difficult loads, even at
relatively low output-power settings (e.g. the 10-watt "tune" setting).

I've tried using this radio with an SGC longwire autotuner I picked up
for cheap at a hamfest, and have had great difficulty getting a
successful tuning. I hit the "tune" button, the radio starts
transmitting, and the autotuner simply chatters away indefinitely. I
can see the radio's SWR indicator bouncing all over the place, but it
never settles down and the tuner never "locks".

If I use the same autotuner, and the same antenna setup, with a
Ten-Tec Scout, the tuner will often achieve a successful lock on the
very same frequencies within 3-4 seconds, even though the Ten-Tec's
"tune" power setting is at the lower end of the SGC's tuning-power
specification range.

The TS-2000 has a high-SWR power scaleback. The Ten-Tec does not
(according to the manual it's SWR-protected in a different way). I
infer that the TS-2000 is probably varying its transmit power
constantly, as the SGC tries different matching combinations, and that
the rapid fluctuations in forward power are "confusing" the
autotuner's match-search algorithm.

So, it's entirely possible that Kenwood uses a transmit-power
throttleback algorithm which is sensitive to the output SWR, rather

than to the absolute level of reflected power seen by the finals.

What you seem to be missing is that it takes only a few
inches of 50 ohm coax on each side of the directional
wattmeter to force a "50 ohm system". 50 ohm coax *IS*
a 50 ohm system, i.e. the load doesn't matter.

All this is easily proven by wading through the math.

Hi everyone!

Anyone know of a nice club or hangout in the Toledo area that caters to cross dressing radio operators? I'm a guy from Toledo who enjoys showing a submissive man a good time in every way. I have so many interests that there probably is some broad common ground between myself and about anyone. I love to talk about BDSM issues and interests, and have been generally regarded as a funny guy to hang out with who has a good head on his shoulders. Send me a message for anything else you'd like to know!
I've attatched a link to my picture below, I consider myself a BBW trapped in a mans body and will be dominant to the right gentleman. (ham radio operators move to the front of the line)

Comcast told to stop blocking Web tool
Published: Aug. 3, 2008 at 2:45 PM
WASHINGTON, Aug. 3 (UPI) -- Broadband Internet customers of cable
television giant Comcast should be free to use file-sharing software,
the Federal Communications Commission says.

The commission voted Friday to order Comcast to stop blocking its
Internet customers from using BitTorrent, an online software
application that enables users to share large movie, TV show and music
files, The Hollywood Reporter said.

Commission Chairman Kevin Martin split with his Republican colleagues
to join the two Democratic members to produce a 3-2 vote against
Comcast. The precedent-setting decision was hailed by supporters of so-
called net neutrality, which maintains Internet service providers
should be barred from discriminating among various types of traffic.

"It was unreasonable for Comcast to discriminate against particular
Internet applications, including BitTorrent," Martin wrote in his
majority opinion. "They delayed and blocked customers using a
disfavored application even when there was no network congestion."

Other commissioners, however, said Internet engineers need to regulate
traffic flow and say the ruling will nudge providers toward
instituting volume-based pricing.

The bastards took away my BDSM newgroups!

<<>>hi JB

thanks for the help when i get some time i'll have to call up
the manuf to see thou perhaps what you wrote above makes the
most sence just i need to be sure

i have certainly used lots of times microwave lmr 400 etc and
andrews cnt400 i typically always get the db both seem to have same
construction styles

i don't really have any way to test them per say they seem
pretty close so if there is a difference i prob wouldn't know until
comscope tells me
so i always wonder if there is something that could bite me
gotta give'm a buzz

thanks very much

Now, lets see... that the "multi-band wire antenna that performs
exceptionally well even though it confounds antenna modeling software".

Yet another 'magic' antenna who's 'magic' cannot be explained!

Of course the claim is nonsense, the antenna can be modelled in NEC...
just the complication is evaluating an equivalent load in NEC terms for
the TL stubs.

You can evaluate the equivalent impedance of a s/c stub of 16.5' of RG8X
(or whatever you used) using the calculator at
http://www.vk1od.net/tl/tllc.php.

For example Z of s/c stub of 16.5' of RG8X at 7.1MHz is around 2.97
+j64.54, so it acts like a quite lossy inductor at that frequency.

Once the feedpoint impedance is found, the transmission line losses and
ATU losses can be evaluated for a system perspective.

Ask yourself why they choose to not model the antenna. Often, when people
claim that an antenna can't be modelled in reality just don't like the
answers.

Owen

I think they did model it, and compared the results against actual
hands-on observations, readings, contacts, etc.

This is why they make the claim NEC is missing something ... they simply
believe their eyes, ears and meter readings and signal reports ...

Could be. I have not analyzed the innards of the beast, but the -870
detects and displays SWR at all power levels -- so it _knows_. That's one
of the bar-graph metering choices and if there's more than a watt or two
out, it will report SWR, good or bad.

Danny,

Thanks for sharing this link. I found the article very well written
and some very good information on SWR and suggestions on antenna
design. Looks like the author is SK, so probably no way to follow up
with questions, as suggested in the article. I'm curious as to when
the article was written. I am just getting back on the air after
several years of inactivity. I am trying to decide what type of
antenna to put up in a 1/3 acre city lot without any tall trees. I'm
thinking about an off-center fed dipole. Looks like an 80 meter
dipole fed with ladder line and using a good antenna tuner would work
on all bands. I don't have room for a full half-wave 80 meter dipole,
but could do a bent off-center fed dipole. The Carolina Windom is
probably what I'm thinking about, but hate to pay their price for
something that could probably be home built. Also considering an all-
band vertical, mounted on the roof of my home.

Thanks again
Vee W7IBB – Utah

This paper takes the view that the final stage(s) in a PA is/are very
much like a power generating plant. And, in a very simple comparison,
it/they is/are:

http://www.degendesigns.com/Downloads/TheEasyWay.PDF

However, that power generating station has carbon piles to sink the
power into and maintain a correct draw for the power the plant is
producing--until generators can be slowed or dropped off line to match
"the impedance" of the load being presented to it. The power plant has
switches and breakers to cut part of its' load to maintain a "correct
match" (or, correct impedance) being presented to its' load, etc.

In our PA's, we do not have such niceties ... the antenna must present
and hold a proper "draw" upon this power being generated in our
tubes/transistors/tank-circuits. If not, either too much current is
drawn, voltage dips, the design parameters of devices and components are
exceed and "something gives." If the load draws too little power,
voltage(s) spike, current drops, and the voltage rating of the
devices/components are exceeded and "something gives."

While the paper, in a round-about-way, does present this in an
convoluted view, it expounds on this/these events to build a case for

obsfucating SWR, forward power, etc.

But then, in old arrl literature, such inconsistencies abound ...
indeed, they can still be found in current material from this source
(arrl) ...

Yanno, every time I read that 10 PAGE PAPER! it just peeves me off ...

Take his statement, "If a mismatched antenna causes power to be reflected back down the line, they reasoned, this power obviously wasn't radiated by the antenna."

He is using this to "poke fun at dummies who don't know what they are taking about", this gives you the hope that "this dummy" is going to simplify, explain and dispel your ignorance on this subject--however, during the next several pages he does NOTHING in this direction.

That statement can be stated more accurately as, "The LOAD is reflected back down the line!" DUH!

However, it can be pictured as power being "reflected", because it sure as heck doesn't get to the antenna where it is anywheres near useful! It sure as heck is going to cause stress and heating in devices and components. A simple FSM will prove this to you in short order! And, just touch those finals to prove the stress and heat.

The guy could state it, stupendously more, accurately in two pages, max--the paper is only a disclosure of the fact he doesn't understand what he is proposing to "teach" others ...

If you can't make a SIMPLE statement (or paper), on a concept, which an average layman can understand, you probably don't understand the concept(s) yourself ... end of story.

The paper stands in tribute to that mans ego ... sad, but true ... :-(

This BS is ALL the way through this paper of his ... reading and
re-reading this paper is going to give me little sleep this night.

Take this on baluns:

"Next, he puts a 1:1 ferrite- core transformer-type balun up at the
feedpoint of the antenna. What happens? His swr comes down to 1.5:1 at
the band edges. Boy, that balun really solved the problem.
Right?.....WRONG! In this case, if his rig would load up (or if he used
a transmatch) he would be much better off without a balun."

YES, that balun did solve his problem! Now the feedline is not the
major element in his antenna, and giving God knows what radiation pattern!

AND, in NO case would "he" be better off without a balun (well, unless
"he" had designed the feedline to be part of "his" antenna. Or, the
antenna was "perfect" and would always remain in that state,
theoretically ...)

I mean this ALL just galls me ... and then new guys coming along read
this crap, take it as "the holy word" since it has "arrl" attached to
it, and it ALL begins again ... ALL over.

Regards,
JS

Here's a simple statement he could have made about reflected
power not being lost:

In a conjugately matched system using lossless transmission line:

Source Power = Forward Power - Reflected Power = Load Power

Let's not forget the possibility that they didn't know how to model the thing. I'm no great shakes at modeling, and that antenna is beyond my prowess at the present.

Of course, I'm mpore likely to assume that discrepancies between computer world and reality are my fault. Some others might assume that the data they input was correct, so it must be the programs fault....

And some on the fringe might say the antenna CAN't work - the computer says it can't!

Cecil:

Conjugately? Gawd man, that terms reminds me of yesteryears (Cecil, that term was an antique when I came along--your age is showing ;-) ...) lol However, the wife and I do get along, conjugately, from time to time--but, THAT IS a story for another day ... <EVIL GRIN>

I believe so, that "reflected power", is certainly causing some of the heating of the semiconductors (finals.) And, some of the "loss" due to SWR is not "lost" (as heat) at all--you can count the power radiating from the transmission line as "power delivered", I suppose ... but I will agree with "him" on one point, it darn sure well ain't endin' up in "SWR heaven!" ROFLOL

At extreme power and extreme SWR I have seen the dielectric of coax puncture and burn ... seemingly, gloriously, dramatically, instantaneously. And, yet, another reason why a balun may be a good idea ... if you grab hold of your coax and it feels warm, suspect dielectric heating and major loss(es) ...

Another thing, with the "correct" transmatch, a couple of coat-hangers can be made to look as right as rain ... at 160m! That don't mean it is right ... that paper burns me bum.

Absolutely, I am NOT making any statement "they" are correct (I have never tried this antenna myself--either as a model or as an actual antenna in reality.)

But, anyway you cut it, and on the ground floor, there ARE discrepancies in the basic equations, formulas and assumptions being put to use in the NEC, someday these will be fleshed out ...

Let's face it Cecil, that man was obviously "being paid by the word"--in our capitalistic society--I can understand that! (However, this paper appears to have been done to "justify" "his antennas" which he was selling at the time. Indeed, it reminds me, very much, of how db has been abused ... I'd say, in this regard, he did a nice job of "Barnum-ing it!" And, was wholly motivated by financial gains. LOL)

And, in that "reality", 100 words are worth 10x as much as 10 words ... and, any inaccuracy will just be justification for more words (and more profit) on another day ... or, more obsfucation ...

The evaluation of this antenna should start with connecting a choke
type BALUN at the input to isolate feedline radiation. A few feet of
wire draped across some tree limbs can let you talk to the world.
There have been an awful lot of hams who have thought they just
invented the best antena out there while talking off their coax.

Jimmie

Kenwood typically looks at forward, reflected current (or voltage) and
adjusts ALC voltage in response to a rise in either. In my TS130, I adjust
tuner into the ballpark, advance carrier, and fine tune for minimum ALC
reading.

Absolutely. The "truth" does have a way of outing itself ...

However, not so very long ago, I did just that ... and being ignorant to just how much the coax (transmission) line was serving as an antenna--I lived in ignorant bliss ... I can't say I wasn't happy! LOL

However, being the control freak I can be, I wanted that antenna "doing its' correct job"--when my ignorance had been dispelled (well, I am working on that one <wink.>)

Man! I have to read that paper one more time! ... LOL

The accuracy of a Bird for measuring power goes out the window for an SWR other than 1:1. Are you saying that if you put an unterminated 3 inch piece of coax on the Bird you have a 50 ohm system? That sounds like semantics rather than Math. In fact you would have a 50 ohm system if you left the antenna port disconnected, Then you could say you had an unterminated 50 ohm system. Real handy huh?

Howard,

I made a homebrew using ARRL information and some advice from this group...pretty inexpensive and it continues to work well after 2 yrs. With a decent ATU, you should get most bands. Mine won't tune 30M. My G5RV is cut for 40M but does fairly well on 80M also. There is a longer version cut for 80M. Mine is copper wire, 300 Ohm window line for the feed and no balun. This comports with the original design, I think.

You can buy center and end insulators from many suppliers, including DX Engineering (or just make your own: short pieces of PVC, for eg...spray painted blk for UV protection).

One thing I might add to my G5RV (after listening to this group) would be some ferrite beads on the coax at the end of the measured window line feed.

For me, Building is more fun than Buying.

Good luck and 73

John

Yeah, yeah. I seem to have contracted a temporary case of dyslexia.
Not only am I getting power and voltage backwards but I'm also
spending money instead of receive it, and voting Democrat instead of
Republican. Probably caused by too much exposure to RF which is
hopefully reversible.

Back to sulking... I just hate making misteaks.

The Bird readings are consistent. In such a case it will read
equal forward power and reflected power (within its accuracy).

This same subject was thrashed out on one of these discussion
groups a few years ago. (I have had a hard disk crash since then
and lost all my notes.) Back then I thought like you are thinking
now. A person a lot smarter than I came up with the equations to
back the proof that a 50 ohm environment is established in only
a few inches of ideal 50 ohm coax. If I remember right, the
necessary length to establish the Z0 of coax was less than ten
radii. It really surprised me.

He proved that a Bird directional wattmeter didn't need any
surrounding coax to establish the 50 ohm environment - that
the internal Thruline establishes a 50 ohm environment all
by itself. Perhaps someone smarter than I who is reading
this exchange can do the math for you.

When light is emerging from glass into free space, how long
does it take space to establish the 377 ohm characteristic
impedance? I suspect that all necessary reflections take place
at the impedance discontinuity and the characteristic impedance
is established immediately.

That is why we can calculate the reflection coefficient at
the junction of two transmission lines with differing Z0s
as (Z02-Z01)/(Z02+Z01).

Frankly, the VF would be what I would be concerned about. Obviously,
the stress of the weight would distort the line from factory specs and
shoot 'em to hell ... not to mention power handling capacity would be
reduced ...

If I were you, this is what I would consider ... but hey, you will
eventually pick it up ...

Then it is not the same antenna as described.

I agree with your implication that an antenna of this type warrants an attempt to minimise common mode current on the feedline... but that is not a part of the design as described.

I have not said anywhere that this antenna doesn't 'work' or does 'work' whatever that means, just commented on their opinion that it defies conventional explanation.

They haven't suggested that the problem is their own limitation in modelling or explaining, so it is reasonable to assume that their implication is that it just cannot be explained in conventional terms and using accepted tools.

I have questioned that assertion, I think it is not all that difficult to model. It presents no more challenges than dealt with in my models of a Bazooka (http://www.vk1od.net/DoubleBazooka/index.htm)and G5RV (http://www.vk1od.net/G5RV/index.htm) assuming an ideal balun.

I know the ideal balun condition appears inconsistent with my first par, the problem is that including the feedline common mode path in the model is complicated by the huge variability from one installation to another, both the length and route. (It is possible to model the antenna with a specific common mode configuration... it is just that is has limited applicability.)

I am tempted to do it one day. Although it isn't the same antenna in that it has a balun, it is revealing. My gut feed is that the antenna with balun is probably not that band on at lease many of the HF bands... more if you ditch the coax section and use open wire feeder to a balanced ATU... but we are moving further from the original.

Having said that, I do think the published VSWR figures at 145.3MHz are fanciful and highlight your average ham's obsession with VSWR, as if that single metric was a good indicator of system performance.

Owen

Cecil - you might like this.

What I got out of Feynman's QED was that the probability for a reflection to take place would be highest at the discontinuity. But that reflection would take place at any point thereafter with some lesser probability - inverse with distance (smaller arrow, different angle). Summing all the little probability arrows (vectors) for various distances results in a magnitude equivalent to a reflection occurring solely at the discontinuity. He used the reflection from a pane of glass as an example. But as you know a change of index of refraction is directly analogous to a change in impedance.

In relation to this discussion, there would be some distance from the discontinuity where the probability of reflection is so low, that beyond that point, the sum total contribution of all the reflections is immeasurably small. I believe it may have been Reg Edwards (sk) who spoke of the distances you refer to. The brilliant thing is that Quantum Electrodynamics substantiates his argument.

hi

i have a general shielding question i realize that overall it
might be a impractical thing to build but looking at it i wonder...

ontop of my roof is elevator room it's about 20x20

flat roof

lets suppose the motor controller throws out 1.7 to 30mhz at
s9+ (all over)

lets say i take a single 20x20 sheet of copper put it on the top
roof (assume i could ground it if need be)

lets say before i put the copper i measured s9

what shielding if any might i see "S" wise??

i understand interference would still be radiating form the rest
of the unshielded structure but wondering if measuring ontop of the
copper sheeting id' observe any attenuation?? meaning would the
signal penatrate that copper? -- and if so around how
much??(alot/very little)

tnx

Is it possible to box up the motor? If you can enclose it, you should reduce most of its noise. Before enclosing it, I would use "RF Paint" to coat the inside of this box. The govt uses EM-SEC paint for their SCI projects.

If done properly, you should be able to nullify 99% of that EMI.

> space without ether is unthinkable." Albert Einstein

Yer yankin my crank.

First off, lets get the Bird manual so that my practical generalizions are set aside, and we can be more specific.
http://www.bird-electronic.com/products/pdfs/opmanual/43.pdf

Originally we were talking about SWR shutdown circuits AND wattmeters although there may be a bit of difference how that is derived, the measurement is usually about a sensing inductance with canceling capacitance in the reverse mode = 0 volts with a 50 ohm termination.

The Bird 43 is a 50 ohm line section. (Page 5) the sensing isolation of the forward and reflected wave are given as "better than 25 db" (page6,7). It tells how the slug is calibrated in the reverse mode. Same as above.

It goes on about Load Power and states: "For loads with a VSWR of 1.2 or less, the power dissipated in a load
(Wl) is equivalent (with less than one percent error) to the forward power (Wf). When appreciable power is reflected, as with an antenna, it is necessary to use the exact load power which is given by:
Wl = Watts into Load = Wf - Wr" -- We know there is something going on here.

Now on to page 8 and here is where it makes plain that the meter and the shutdown circuits really don't measure SWR but forward and reflected wave and I don't really think there is a whole lot of math going on in the protection circuits of the radios.

The Bird can be used in other than 50 ohm systems (page 16,17) but now you have to figure out the actual power dissipated in the load, and the power dissipated in the coax. Examples are given.

If you use the (Z02-Z01)/(Z02+Z01) for the reflection coefficient, Fine! But the line must be properly terminated resistively. Great for discussion but real world gets complicated fast. As soon as the load gets reactive, the phase between the voltage and current are different and the length of the coax and it's velocity factor now contribute unless it is really short compared with the wavelength.

What we are really talking about here is the short piece of RG-174 (or whatever) from the radios' sensing circuit to the antenna connector where there was a dummy load to set the reflected nulls and output leveling, reflected indication and/or trip point. Now we remove the dummy load and there is a length of coax and an antenna there.

Now tell me the truth, if the SWR is above 1.2:1, does that mean the radio is making more power? No. Because I can read 100 watts out of a radio into a tuner and 195 watts forward and 175 watts reflected out of the tuner on 80m. I KNOW my MFJ tuner isn't a passive amplifier. Go back to Pp 6 and 7. It actually reads scaler because it is reading inductive (magnetic) and

capacitive (electric) so the output "power" is calibrated for known forward voltage scaler after being calibrated for 0 reflected voltage scaler at 1:1 SWR. Beyond the 1.2:1 case, the power reading is NOT CALIBRATED or accurate, but we can make inferences and guesses, and the ratio is useful. There are also inaccuracies due to the 25 db directivity isolation which adds some forward to the reflected and vice versa.

For more on that see:
http://www.bird-technologies.com/techapps/app_notes/StraightTalkAboutDirectivity.pdf

When they does get down to some hard numbers they can be wanting. Re your example above, they say "Since a 10:1 swr on 100 feet of RG8U at 4 Mhz increases loss by less than 1 db, don't worry...". The loss on 100' of RG8/U at 4MHz with a 50+j0 ohm load is 0.35dB, the loss with a 5+j0 ohm load is 1.64dB (a bad case of load end VSWR=10), some 1.3dB higher and clearly not less than 1dB higher as he explains. Since it is not clear, some readers might even think that the statements apply to indicated VSWR at the source end of the line.

When they get some things that are easy to check quite wrong, it does cast doubt on the credibility of the paper. Their point in this case about band edge VSWR is probably fair if qualified for usual configurations... but it needs qualfication and the premise they use to support the assertion is plain wrong. Why didn't they just correctly state the increased loss at VSWR=2 in support of their argument (it is about 0.1dB)?

You could pick through the technical content of the paper in this way, and try to discover if there is any real value to the name dropping... but it is a mix of good stuff and not so good stuff. There is still a place in the world for text books.

Nevertheless, I sympathise with them trying to find good reviewers... it is a challenge.

Owen

> SWR other than 1:1. Are you saying that if you put an unterminated 3

If by "measuring power" you mean determining the average rate of flow of energy past the sensing element, you are not correct. The power can be calculated as the indicated 'forward' power - indicated 'reflected' power.

This is a property of any directional wattmeter of this type when the sensor is calibrated for an impedance that is real (ie non reactive), irrespective of the load or the type of coax that might be attached to either side of the instrument.

Of course, practical circuits are not ideal, and errors are introduced in all measurements. Some ham grade instruments are even less perfect.

The reason that Bird suggest that you can get an answer for power for VSWR < 1.2 by ignoring 'reflected' power, is that 'reflected' power is less than 1% of 'forward' power and ignoring it does not introduce significant error compared to other system errors.

You would be adding a nice lightning attractor (not lightning rod) with the grounded copper sheet which if the right conditions occured would also set your house/apartment building on fire..... According to the ham exam the intference is their problem. Maybe you could use some ferrite loops/beads on your power leads to see if you could stop it.
Maybe not theanswer, but it's one way to look at it.

You need to wade through the math. No matter what the phase,
the Bird directional wattmeter reads the forward or reflected
power referenced to its 50 ohm Thruline plus or minus 5%. If
that were not true, the Bird directional wattmeter would not
meet its published specifications. The phase is taken care of
when the sampled voltage and sampled current are added for
forward power or subtracted for reflected power.

> Now tell me the truth, if the SWR is above 1.2:1, does that mean the radio
> is making more power?

I certainly hope that is a rhetorical question. In a matched
system, the reflected power is part of the forward power. In
a matched system, the reflected power is redistributed back
toward the load and becomes a percentage of the forward power.

Source Power = Forward Power - Reflected Power = Load Power

If the SWR is not 1:1, the forward power must necessarily be
greater than the source power. Maybe the following web pages
will help:

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and the thickness of
the film are such that a phase difference exists between reflections of
p, then reflected wavefronts interfere destructively, and overall
reflected intensity is a minimum. If the two reflections are of equal
amplitude, then this amplitude (and hence intensity) minimum will be
zero." (Referring to 1/4 wavelength thin films.)

"In the absence of absorption or scatter, the principle of conservation
of energy indicates all 'lost' reflected intensity will appear as
enhanced intensity in the transmitted beam. The sum of the reflected and
transmitted beam intensities is always equal to the incident intensity.
This important fact has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction of
light."

A simple example should alleviate your confusion. Assume a
one second long lossless transmission line. Source power is
100 watts. Forward power is 200 watts. Reflected power is
100 watts. Source power is 100 watts.

How many joules are in the one second long transmission
during steady-state? Hint: it is *NOT* 100 watts.

> much??(alot/very little)

First, please know that a mesh is nearly as effective as a sheet -- and much, much less expensive. I doubt you can afford that copper sheeting. Can you cover the roof with metal mesh? (Using this principle, I draped some hardware cloth over my sprinkler valves & wiring and it stopped the false triggering of the solenoid valves from my 40m antenna. Effectiveness will vary, depending on the coupling mechanism; coupling via the building wiring may be as much of a problem as the radiation effects.)

Unless you are creating a true RF-tight enclosure (100dB of shielding effectiveness is typical for them.) nobody can tell you how much suppression you'll get, since the situation affects the numbers.

Getting into a struggle with a building owner, especially if it's your landlord, may be a bad idea. However, he is legally not allowed to operate a serious interference source and maybe can be forced to suppress the EMI at the source. Our local power company, bless their hearts, came out and completely fixed some power line EMI I had a few months ago. They appreciate the interference laws but not everybody does.

Yes, absolutely!

I've told this story here before ...

My first HF antenna was a 10m vertical dipole I made out of copper water pipes. Using a tuner, I could work 15m with it, but not 20 -- it needed more metal. So, I grabbed an alligator clip lead and electrically added an old 8-foot ladder that was literally laying on the ground next to the dipole. This enabled me to get a good SWR and I immediately worked Hawaii from here near San Diego.

One wag asked if I was feeding it with ladder line. No.

I looked at adding these to the line loss calculator at http://www.vk1od.net/tl/tllc.php , but the clever people at Comscope prevent copy and paste from their PDF datasheets. As a matter of principle, I do not retype figures to minimise the risk of errors.

I guess we might see that policy applied to the Andrews products in time.

The Comscope takeover and subsequent web changes has made finding info on Andrews products so much more difficult. Still, there are always the competitors.

The products you mention competes with the LMR series, there is probably very little difference, but if you are fussy, buy the products for which you can get suitable product documentation and insist on no substitution.

Hello, and in a general case one has to be careful in dealing with the
concepts of "forward" and "reflected" when talking about power. It can
become an issue when source impedance, tranmission line characteristic
impedance, and load impedance all have different values. The "matched"
value corresponding to no reflections might not be the value for maximum
power transfer from source to load. In this general case incident
(forward) voltage or current from the source becomes a function of
mismatch between the source and the reference impedance (e.g. 50 ohms) and
the mismatch between the load and reference. When the source is matched
this dependency vanishes and the incident power is the same as the
"available" power (Vsource^2/(4 * Real part of source impedance)) from the
source.

The source can be "matched" to the input of the transmission line feeding
the load but not be conjugately matched to the transmission line/load
combination.
Conversely, we can have reflections present at the source-line interface
for conjugate match conditions. Sincerely, and 73s from N4GGO,

Note that I specified an ideal lossless transmission line.
In a lossless system, if a conjugate match exists anywhere,
a conjugate match exists everywhere. My assertion was a
conceptual statement about an ideal example.

> Conversely, we can have reflections present at the source-line interface
> for conjugate match conditions.

I was also assuming a 50 ohm source with a 50 ohm Z0-match in a
lossless system. I should have specified such. Here is what I
had in mind.

XMTR---50 ohm coax---+---1/8WL 300 ohm twinlead---(97.3-j283.8)

There is a (close enough) 50 ohm Z0-match at '+' :-)

I've reworked and reinstalled my Bugcatcher antenna.

I'm having a bit of a problem with soldering the taps to the coils though. Seems road oils and general tarnishing has made it a bit difficult to get a clean soldering surface.

I know of a lot of ways to clean the surface, but most are a little rough on the coil or time consuming.

Anyone have any tip or trick to get the surface clean, shiny, and easily solderable?

note, I've tried some solvents without much luck, and any solvent has to not eat up the plexi coil form. I've tried steel wool, but it can't get to the interior of the coil, and regular sandpaper is going to eat the wire up.

I have even considered an acid flux bath, followed by a long water rinse, but that's always been verboten for electrical work.

Hi Mike,

It seems you've been out of electronics production for a verrry
loooong time. Acid flux is commonly used for environmental reasons.

Try dipping it into a small portion of Coca Cola overnight. The
Phosphoric Acid in it will strip anything....

Cecil:

I believe so ...

However, you have been lifting weights with your brain. These things look elementary to you; your only mistake is you do not strive for even a simpler example, to let those wishing to, catch that first step ...

The lossless line is a key. Remember those lines of force around a magnet which can be seen with some iron powder and a paper?

These are being stored within the ether; you are seeing the only feeble proof of the ethers existence--magnetic lines of force, in that simple experiment. Remember the plans to store energy in a superconductor configured in an endless loop? Where do people think that energy is being stored? In the electrons and other particles? Naaa ... it is being stored within the ether--in magnetic lines of force ...

You lossless line has no loss, simple. 100% of the power being stored in the ether is being gotten back from the ether (and your lossless line is a superconductor.) And, when that condition exists, the workings of the antenna become a bit more clear (visible) ...

Art says some of this in his "ramblings", most just don't look for it ... Art just obsfucates beyond recognition (or fubar!)

35 years to be exact. We just about had it beat into us that you don't use acids near electronics.

But it does stand to reason that a good water rinse will remove acid flux very well. Certainly the flux removers for rosin can be environmentally and health unfriendly.

> Try dipping it into a small portion of Coca Cola overnight. The

Probably take about 3 liters for a Bugcatcher coil - around 6 inches diameter, and about a foot in length.

But Thanks for the tip, I'll give it a try tonight. Might use Pepsi tho' ;^)

Jasco paint stripper? Will work for paint, road oil, road tar, plastic insulation, etc.

For corrosion, Richards ideas seems plausible ... perhaps employ a combination of methods?

The active ingredient is Methylene Chloride, cheap brands use lye; lye just ain't that great, IMHO ...

Hi Richard

I once made a small tub to hold the rusty part and filled it with a solution of water and washing soda (http://www.stovebolt.com/techtips/rust/electrolytic_derusting.htm) . A small DC current is then conducted from a metal part in the solution to the rusty part. The rusty part got shiny after a few hours.

Assuming you want to avoid an aggressive chemical attack, methinks
you're on the right track. Instead of steel wool, emery cloth, or
sandpaper, use a damp cloth and some abrasive kitchen cleanser
(Comet). Wrap the small cloth between two of the turns (using a
tweezer to pull it through), apply some cleanser, and alternately pull
on the ends back and forth. Kinda like shoe polishing. The cleanser
should remove any grease and grind off any oxidation without removing
the wire plating. When done, wash with water and let dry before
soldering.

Even better. It is known to take a few radii to clearly
establish the characteristic impedance. The effect apparently
can be measured and there exists an equation for it. I just
had a flashback that it might be in Chipman.

If that is to imply that common mode current only exists on the dipole side
of the common mode choke, it is a mistaken analysis. A common mistake, but
wrong nonetheless.

FWIW, I "pickle" the heavily oxidized copper antenna
wire I have to solder by wrapping a paper-towel sheet
around the joint, pouring a tablespoon of "Lime Away"
on it, waiting half an hour and then unwrapping and
rinsing it throughly with tap water. The copper has
a reddish, 'blistered' look and soaks up solder like
a sponge. I make it a point to tin all of the "pickled"
copper on either side of the joint as well as the joint
itself.

The prohibition against using 'acid-core' solder on
electronics was that the acid flux was actually a solid,
would remain on the connection and be activated
by moisture later, eating away the connection and
the wires. The active acid in "Lime Away" is good
old sulfuric, which is washed away in this case by
liberal amounts of applied water or later rainfall.

the copper sheet would likely not help shielding of the rf. it would
conduct the currents nicely and maybe redirect the fields a bit, but the
current would conduct out to the edge, right on around to the bottom and
radiate just as well down toward you as up away from you. I would assume
from your reference of an elevator room that this is a relatively tall
structure, so grounding is not going to help. the lengths of the ground
leads would make them also nice radiators for the rf from the motor, perhaps
making it worse if they were close to your antenna. Better to filter power
lines to the motor and controller and stop the noise inside the case... once
its out there is very little you can do to stop it.

What gets me:

1) We are about to reward the crooks, charlatans and greedy by making good their gambling debts and outright thefts!

2) No legislation/laws/regulations have been enacted to secure there is not an immediate repeat of the same. (I'd be surprised if anything meaningful is ever done ... I can't make that big a leap of faith)

3) Those "poor" who are caught up in this scam are about to become homeless, whereas the rich crooks are about to purchase nicer homes at near fire-sale prices.

4) All of this devalues the dollar and MY MONEY, and, oh yeah, YOURS TOO!

5) Etc. ... <a-look-of-doom-and-gloom>

Regards,
JS

Hi Walt,

It might be used as a gas additive - not necessarily in the tank, but
certainly useful at the pump.

< snip >

I posted the instructions for a Channel 2 Yagi a few weeks ago. They were
acknowledged and I've been waiting anxiously for some feedback.

Curiosity got the better of me this afternoon, so I built the thing
myself -- exactly as described except for the second director, since I was
losing the light and three elements proved the point.

With just the folded dipole at ten feet, I got a recognizable KCBS picture
from 124 miles. Bad snow, noisy sound and no color. Joe, a dedicated Jets
fan, would watch this picture but his girl friend would not.

When I added the reflector, the snow and the sound got better. When I put
it up to fifteen feet I had color. When I added the first director and
returned it to fifteen feet, the snow got a lot less and the picture was
quite watchable. The girl friend would say, "Gee, Honey, that's a pretty
good picture. Can we get free HBO, too?" (They never understand ...
never.)

I measured the signal with my old analog signal level meter and got negative
16 dBmV, which looked about right. Another director should add only a dB or
two. Maybe I will try a preamp and see what that does. Trouble is, Channel
2 suffers from impulse noise (electrical appliances are usually the cause).
Antenna would need to be elevated to reduce that problem.

WCBS has an insignificant 1 dB more power than KCBS but their antenna height is a lot less, which impacts Joe in Connecticut. However, his distance is less, 100 miles vs. 124 miles.

A 3el 6m yagi would work very well, all you need is a 50 ohm to 75 ohm
adapter @ about 20 feet. Use a small TV rotator, and when your not watching
ch2 you can try calling CQ on 6m.

This experiment will probably turn into a 6m Yagi, anyway, since we won't
have an analog Channel 2 after DTV takes over in February.

I'll need to check the polarization for 6m. Right now I have a couple of
j-poles for 6m, vertically polarized. Thanks.

Make sure to read the PDF file too. Apparently stainless steel will
produce chromate in the solution if used as an electrode.

http://www.pieperpower.com/employees/msds/Sodium_Chromate.htm

or other chromate - they are all mostly bad for you.

Since my coil has some stainless parts in the current path, I'll try
suspending it so that they don't touch the solution, and rotate the coil
to clean.

Doug is someone who has fathered children and does nothing to support them
or have any involvement with them. He is one of the reasons we all pay
higher taxes for social welfare progams and why some people will rob, rape
or murder you because they had a father like Douglas.

He is a wart on humanity.

I doubt that any antenna an amateur is likely to build has some physics not adequately modeled by the math in NEC. Exactly what might be these discrepancies in equations, formulae and assumptions? Considering that NEC has had decades of validation against actual measurements and a lot of really, really smart people looking at how it works, I'd be kind of surprised.

However, I can also easily believe that an amateur (or professional) could build an antenna that has measured performance different than expected from their NEC model of that antenna. The differences would lie, most likely, in these areas:
1) Inaccuracies in the model itself. Things like earth properties (NEC assumes uniform dielectric, it isn't) are an important source of error for antennas close to the ground. Most amateur models do not include a very good model of the surroundings (supports, trees, feedlines, etc.)

2) Inaccuracies in the measurements or not measuring the right things. A good example is using NEC to get feedpoint characteristics, then measuring at the rig, and not properly accounting for the transmission line, particularly if the feedpoint Z is reactive.

In the professional antenna world, if someone models an antenna, then builds it and tests it on the range, and the measurements differ from what the model predicted, the usual assumption is that what was built differed from what was modeled, or the measurements were off.

I don't believe the above it correct. Indeed, if you will only review
my past objections and reflections on how "the NEC engine" demonstrates
"differences" you will be focused at the "focal point" of my "inquiries" ...

Look, the dipole, standard monopole (1/4, 1/2, longwire, etc.) is NOT in
debate. Indeed, it is like NEC was designed to "explain/model" these, DUH!

I could pick apart the above, attempt to poke fun, etc. -- however, I
would much rather join forces and attempt to focus on the points which
would lead us to real answers -- i.e., the arrl and illiterates have
already done enough damage, let us pursue a more productive path?

Leave us leave our minds open, OK?

Regards,
JS

And damn, and DAMN, and well DAMN ...

If you want to build something from a 19?? to 1950 (or beyond?) publications, do I stop you? Is this what "you have you back up your ego about?" It this what threatens you? If so, go ahead, go to your grave with your pursuits, without my critique! ...

I am here about what "I AM", about "WHAT I THINK", about "WHAT I SEE", about "WHAT I SUSPECT", about "WHAT I WONDER", about "MY QUESTIONS TO OTHER MEN/WOMEN", about what I simply want to think about and want answers to ... yanno, I think you are really endangerd by those "others" here, I find ... Cecil, where are you? <evil grin>

If you can't participate, if you think I am am an idiot, if you think I am a moron ... could you do it politely until I give you reason to do differently ... indeed, I may feel threaten my "moronic brains" and respond ... please don't take insult, just reassure me I am not wrong ...

Regards,
JS

Look, that got "corrupted" in my frustration, I am not a writer, I just attempt to bring my skills up to speed to participate here ...

Let me change all that:

If I can't think here ... If I can use this as a "note pad" ... If I can speculate here ... If I can't search for others here, if I can't use other as a "backboard" here ...

... then let it all be damned ... I am an idiot ... and let's look over your past, present and future questions, speculations, advances, etc. ...

Regards,
JS

Not in the least necessary from any perspective; but I can see why
some modeling would be impossible to confirm against the data offered.
Afterall, if the prognosis of, say, netzheimers were based on a ï¿½0.1dB
DNA error, then all bets are off in proving sanity.

Knowledge may give weight, but accomplishments
give lustre, and many more people see than weigh.

Today, I added the second director and the signal level actually went DOWN a
dB or two. I couldn't believe it, so I took the second director off and
the signal came back up.

Maybe the extra director is throwing off the impedance, and making any
additional gain disappear. The folded dipole is terminated in a 300/75 TV
balun and these are not precision instruments!

I noted that the MFG-259 analyzer did not show one distinct dip in the SWR.
There were dips all over the place. I realize that the -259 is 50 ohms and
I was reading into a 75 ohm system but I don't think that would greatly
affect the dips, other than how close to 1:1 I'd see.

Although NEC can't model everything (for example, it can't model a patch antenna containing dielectric), this model is not at all proof of that. All it shows is that models can be carelessly or intentionally constructed in such a way as to cause NEC to malfunction. An experienced EZNEC or NEC modeler would immediately run an Average Gain test and seen that the reported gain is about 16.7 dB too high due to numerical problems. If desired, this can be subtracted from the reported gain to give the gain that's much closer to reality.

A resistance, the jagged schematic symbol that we use in basic circuit analysis, can be and often is used as a simple model of a resistor. But anyone who has ever done any electronic design or analysis quickly discovers that this model is adequately accurate only under some limited group of conditions -- for example, it's a lousy model of a leaded resistor at 10 GHz --, and any calculations made using it will be far from measurement of a real resistor (assuming the measurements are capably made). Like the resistance and all other models, NEC also has limitations and boundaries over which it's valid. And it can be misapplied to produce just as egregiously bad results as using a resistance to model a leaded resistor at 10 GHz. In this case, the model violates at least one NEC rule by spacing two 40-foot #14 wires 1/2 wire diameter (0.032") apart. (NEC guidelines specify that parallel wires should be at least several wire diameters apart.) It would be a great challenge to actually construct this antenna. But, even at that, the NEC results are probably not bad once the average gain correction is made.

Here's the model in .NEC format for those who don't have EZNEC. I've changed the current source to a voltage source which simplifies the model without making any difference in results.

A lot of people are aware that some knowledge and skill is necessary in order to construct a good model which will give accurate results. What's not so widely appreciated is how difficult it is to make decent measurements of even such seemingly simple things as impedance, let alone gain and pattern.

Some years ago I was at what was then NOSC (Naval Ocean Systems Center) in San Diego, where they had the very best equipment to do full 3D pattern measurements of antennas mounted on carefully constructed and accurate scale models of U.S. Navy ships. They were also modeling the antennas and ship structures with NEC-4. One of the engineers confided to me that they'd learned that when the measurement disagreed with the model result, the model result was probably better. Of course, these people were very highly skilled in using the modeling software and how to avoid and detect its limitations. But they were also very highly skilled in making the best possible measurements.

A claim by an antenna manufacturer or creator that an antenna "can't be modeled by NEC" very often means that NEC's accurate results don't back up the manufacturer's or creator's inflated claims. If the claim includes a statement that some alleged physical rule or phenomenon ("critical coupling" comes to mind) isn't "accounted for" by NEC, you can be certain that the disparity is due to inflated claims rather than a shortcoming of NEC. There are, of course, some antennas that truly can't be modeled with NEC, for example a patch antenna with dielectric between the patch and ground plane. But those of NEC's limitations that aren't apparent from the basic program structure have been pretty well discovered and documented in the 30 years or so it's been in use.

Antennas are being designed every day with NEC and EZNEC which provide critical communications functions for military and government agencies, aerospace companies, space agencies, domestic and international broadcasters, scientific researchers, and many others. Many of those antennas have been carefully measured and verified before being put into service, and countless of them are in current use. I personally have designed a number of antennas with EZNEC, tested physical prototypes at a professional range, and seen them put into daily service performing critical functions as designed.

I should have said "experienced *and not careless*". The average gain is
about 30.4 dB, not 16.7.

The wires are just about one wire diameter, not 1/2, apart.

This antenna is a very difficult one for NEC. In a few minutes of
fiddling, I couldn't get a decent average gain at much less than about
0.3 foot wire spacing, and then it required specific segmentation. I'll
modify my earlier statement to say that this is an antenna that is
indeed pretty difficult for NEC to handle. But it's easily recognized as
such by looking at the average gain result. If you don't know about the
average gain test, look in the EZNEC manual -- included also with the
demo program -- index under "Average Gain". It's an important and
valuable tool.

thanks for the help Dav, i sorta feared a simple sheet wouldn't do
much but wanted to double check

seems the device does not radiate along the power lines it just
radiate s of the device itself

it's about 12x12 x12 inches or so the motor controler is inside a
tight heavey metal cabinet the only rf measured is from that
device itself

my thought is to perhaps find a way to build copper mesh 'box' i
can place over it perhaps that would do the trick? it has to be
mesh as the controller gets pretty hot and is fan cooled

3338. Effective length of braid dipole leg?

I want to make a flexible, portable, vertical 10M dipole from coax by folding back roughy 1/4 wavelength of the sheath and taping it in place.

I would not expect the sheath to perform like an equal length of solid or stranded wire because if the extra length of wire. Is there any theoretical way to compute a factor, or do I just keep snipping until I get lowest SWR at the desired freq?

Ken KC2JDY

galvanized 'hardware cloth' that has about 1/2" mesh is plenty good for that
and can be easily soldered.

SUPRGAIN.EZ was a complete accident from many years ago.
I noticed that the closer together the wires were, the
higher the reported gain. When it got to about 5 dBi
omni, I knew I had done something wrong.

All I was trying to do is show there are certain things
that NEC cannot do. I suspect that modeling Art's antenna
is one of those things.

Ken,
You'll have to do some 'tuning'/trimming no matter what you make the thing out of, wire/braid. So, why not make that braid adjustable? Let it slide up/down just a bit (carry lots of tape). No two installations are ever the same so being able to 'adjust' things is reasonable.

Be careful about the end of the coax sheath where the
voltage can reach levels high enough to arc and/or
give severe RF burns.

> I would not expect the sheath to perform like an equal length of solid

A web page gives 460/f for the overall length. I would
use the standard 468/f and trim to resonance.

Let me see, is there a way to "carelessly or intentionally" construct
data into my formula to compute the volume of a sphere to make the
formula "malfunction?"

Nope! Guess that formula is returning valid results! Nice being able
to have real confidence in it! ;-)

I've found this method to be very ineffective in choking common mode feedline current -- an effective sleeve requires a high impedance for the outer coax structure, which this doesn't provide. So your dipole impedance and performance will depend on the length and orientation of the feedline and the ultimate path to ground for the common mode current. You'll probably need to trim it when connected to the rig you'll be using, grounded (or not) as it will be when used.

What is the volume of a sphere with the measured dimension of
a chord = 1 meter?

That was too easy!

73's

That's unfortunate, because I am looking for a simple arrangement.

What if I just hang a wire dipole vertically from the mast (= bendy
Black Widow crappie pole) with a PL-259 at the feedpoint? How much
would the coax feedline have to stand off from the dipole to keep from
interfering with its operation? I can't pull it too tightly away or
the pole will bend.

The vinyl on the outside of coax has some fairly poor RF insulating
qualities.
A number of CB antennas were built like this and the end of the braid
would often arc through the vinyl if illegal power was used. One of
the manufacturers changed the way they were making them by embedding
wires on the inside of the fiberglass tube that was used to house the
antenna. The wires replaced the shield. Another design is to replace
the folded back shield with a trumpet shaped tube. This is common
today on WiFi antennas. I have one for 6M that has the coax running up
through some EMT tubing. The coax is held centered inside the tubing
with little blocks of styrofoam. A few years ago the PVC coupling I
was using to fasten it to the mast cracked. I repaired it by wrapping
with fiberglass and have had no problems since.

Which is to say even with your confidence and your formula that you
don't know. It demonstrates you can neither construct careless nor
careful data. This was anticipated and all would note that Sarah Lee
could answer her own questions even if she couldn't answer others'.
(Did they draft Cecil to Sedona last weekend for her rehearsals?)

Brett, let's just cut to the chase and point out all of your
"objections" to modeling are offered with rather pale logic and even
less demonstrables.

Simpler yet, you are just trolling - but that isn't groundbreaking
news here....

Or, let me summarize, by stating an example:

Take two boxes, mark one "TROLLS", the other "NON-TROLLS."

Now, put members of this group (or from your life experience--that'll work also) into the two boxes, sorting as you see fit.

Now, if you notice that one box is full of all those who agree with you and who you worship, and the other is full of all those not agreeing with you--you don't have a "troll problem" at all!

A very long distance I'm afraid. You might be able to live with the common mode current. Otherwise, a larger diameter air-insulated sleeve or some other decent isolation method like a J-pole are about all I know of that would reduce it. Even those methods, though, can result in some common mode current depending on the feedline length due to mutual coupling between the feedline and intentionally radiating part of the antenna.

If you really want to avoid common mode current on a high, elevated vertical, you need to first effectively choke the conducted current with a high Z sleeve or J-pole type decoupling stub. Then you need to take care of the coupled current. One effective way is to use two common mode chokes ("current baluns") spaced about a quarter wavelength apart along the feedline. The Isopole took care of both by using two flaring sleeves.

There are a lot of antennas being used out there which have no special effort taken to suppress common mode current, and they seem to function well enough to satisfy most users. But it can be a problem in some cases.

It is trolling enough that you insist it would need three of your
examples.

Or you could simply answer how your confidence and formula would find
the volume of a sphere with a chord dimension of 1 meter to greater
accuracy than NEC models exhibit in finding far more characteristics
of antennas.

Let's see, does your confidence rise to respond to your own
sub-topic's assertion, or do you chase after the troll's crown?

Guten Tag Radio Aficionados!

Great opportunity to get out and have some fun with ham friends. The special table is reserved for those wearing their callsign hat or badge. Come and celebrate Yuri's 50 years in ham radio and check out this site for future Ham radio conventions the MountainView Resort in Glen Spey, NY.

As you may know, the Ardmore Mansion has been elegantly renovated this past year. Our motel units are currently being refurbished and the Black Sea Ballroom and Brew Pub are beaming with restored wood floors and new interiors. Our new pavilion is almost finished and will be ready for large outdoor events.

We are gearing up now for Oktoberfest, which will be held on Columbus Day weekend, October 11-12, bigger and better than ever. We will be featuring authentic German food and specialty Oktoberfest German beer, vendors, and games for adults and kids alike! The highlight of the evening is Jagermeister's own Fritz's Polka Band, performing live at the Saturday night dance. Also, for two nights only, Dark Forest, the area's premier Halloween events company, is presenting a Haunted House at neighboring Burn Brea Mansion. They will be celebrating the mansion's 100th anniversary by charging the same rates ($10 per person) they charged the last time the show was presented, 10 years ago! Transportation to and from Mountain View will be provided at no additional charge.

On Friday night, October 31, we are hosting a Halloween Masquerade Ball, with costume contests, dancing, and a frightfully fun time for all! Ages 21 and over, please. Then, on Saturday November 1, we present our Fall Festival & Market. Come and sample the best of the area, and enjoy the leaves changing colors while sipping on Mountain View's specialty cider.

Please check the web site for the latest news and programs at www.MVresort.com and check out or download the posters for more information. Spread the news, bring a friend and see the progress at MountainView. We are building our mailing lists and soon will have regular newsletters informing our patrons about the latest and upcoming events at the resort. Please pass on email or postal addresses so we can stay in touch.

See you at MaountainView!

Yuri and the crew
please email me if you are coming

The large-diameter sleeve is impractical in my app because it make the
antenna non-flexible for storage. Also expensive.

My principal use will be QRP. I will stick some ferrite beads on the
feedline and hope for the best.

The most I would use non-QRP would be 25 watts SSB.

I would argue that the gamma match on a 1/2 wave radiator is so close to the efficiency (or better than) than the 1/4 matching section of the j-pole, that this 1/4 matching section only becomes an encumbrance and should be avoided (if you don't mind the length, consider lengthening the 1/2 wave section to 5/8 wave.)

However, it (the gamma match) is absolutely more efficient than the coil/cap circuit in this design mentioned above.

A homemade coaxial cap. (a few refer to is as trombone cap) is easily constructed for the match--meaning parts can all be found around the home or from the nearest junk pile!

And, don't forget the UnUn ...

IMO, it's hard to beat my "Pico-J" made with 300 ohm twinlead.

Somehow, I have missed the importance of the "pico-j" ... how come no
link to some info on your webpage (I am looking at: http://www.w5dxp.com)?

I just might pickup a hunk of twinlead (or space/tape a couple of wires
together)

It actually seems to be a Zepp, rather than a J-Pole.
1/4WL feeding 1/2WL.

OK, we have had a similar discussion before, part of your text here:

"In much the same way a Zepp or a J-Pole is not a 3/4WL
radiator even though they are 3/4WL long, a gamma match
on a base-fed 1/2WL vertical doesn't yield a 1/2WL
electrical radiator. For this reason, the length of a
gamma match should be considerably less than a wavelength.
A good rule of thumb is probably in the ballpark of less
than ~6% of a wavelength. Your idea seems to require about
16% of a wavelength."

I remember ...

It would be fairly hard to use a small antenna if no one
were around to make any... :/

>Same situation with
> hams as they fight at the very idea of the possibility of small
> efficient antennas that like the Universities do not want to hear of
> the possibilities

Most that deal with small antennas eventually find that there is
no free lunch. This attempt at small antenna perfection has gone
on since way before I was born. Of course, being that you disregard
all previous science, I guess you missed the memo. :(

> One doctorial student at Illinois University in Central illinois
> stated that they have so many requests for review of antennas by the

And likewise, neither have you.. So where is the beef?

So to sum up puting U of I to one
> side, is there anybody in Industry who desires small antennas or
> Universities investing time in such things ?.

Yes. But they deal with the real world, not a bunch of conjered up
voodoo science.

> When O when is anything going to happen in the small antenna areana or
> is the need actually ficticious
> because of diminishing returns with the use of such?

You can't polish a turd and turn it into a diamond.
Only people with limited room are likely to be interesting
in accepting a decrease in performance, vs using full size
antennas. The only place you see me using small antennas on HF
is mobile. And while I've spent a good deal of time trying to
optimize the efficiency of those antennas, I have no delusions
of grandeur when it comes to their efficiency vs say a dipole.
I happen to realize that there is no free lunch.

> What Universities
> in the U.S. that are serious about small antennas and what have they
> produced in the last couple of years?

Why don't you ask them. Could care less myself..

>If they can't or deny the
> possibilities then why fund them?

I don't.

>It is your money. But then who
> cares, we have antennas already so we don't need anymore
> especiually when denial of the new suggests that all is known.

Good point, and I agree. I really don't care. I like big manly
efficient antennas, not air cooled dummy loads on a stick. :/
If you say all is known, I'll take your word for it.
Of course, I know that's not true, but if it applies to you,
it's good to know a man who knows his limitations.
Clint Eastwood would be proud. :)

Funny you should mention that. As, when you peek closely under the hood of the NEC engine (at least the one I use and have the source code to), it does have a bit of what you call "voodoo science", IMHO ...

> Only people with limited room are likely to be interesting

Don't forget us guys who are over 50 and getting tired of maintaining large hunks of metal in the sky and fighting the force of gravity Gods to do so (in more ways than one! And, not to mention neighbors, rules, regulations, etc.) With the price of real estate being manipulated near "Hong Kong Prices" (what is that, about a million dollars a sq. ft.?), reduced size antennas will only increase in uses and demand ...

One design that I saw that you may try it to just use a 1/4 wavelength of wire at the end of the coax. Then about 1/4 of a wavelength down the coax you use a choke. It could be a coil of coax or it could be the beads at your power level.

I have not tried it, just saw it in one of the ARRL books.

Richard:

Doesn't it even embarrass you in the least to make such statements which the mere application of common sense will declare an outrageous lie(s)?

The code which comes into play when a gamma match configuration of elements is defined and handed to the NEC engine, along with the proper pf to cancel the inductance of the gamma-rod, should be proof enough ... to any legitimate software engineer with "an antenna hobby." Indeed, any man with common sense who can understand the equation(s) being called to play and their very (rounding/guessing) nature ...

Download the code and locate it yourself! It comes in Fortran, Basic and "C" flavors--at least ... if you are intelligent to understand this conversation on even a basic level, you should be able to accomplish that ...

And then, of course, there is this little jewel:

http://assemblywizard.fr33webhost.com/v1p1comp%20All%20sorts%20of%20small%20antennas%20better%20by%20heuristics%20.pdf

Citing antennas which NEC has a "bit" of a problem modeling. The
author, a professor and amateur, notes that the power is not being
"lost" as heat ... so you propose it is being transferred to another
dimension?

You remind me of the guy who took the boat trip to see the ocean. He
departed on the boat upstream at a large river. No one ever bothered to
tell him that he had reached the ocean ... he fell overboard ... among
his last cries, was heard, "And, I did so want to see the ocean before I
died ... gurrgleeee ... "

> Richard Clark, KB7QHC

Due to the insane nature ALL of your postings have taken (and yes, I have noted you have refrained from using quotes from Shakespeare to validate your arguments), all that is left is to point out your insanity.

Restating what has been restated has lost all hope of getting though to you ... a shrink would be required now ... perhaps a family intervention?

You can prove my time carrying on any discussions with you is valid, if only you can download the source to the Numerical Electromagnetic Code, compile and link it, and feeding it a problem containing a defined gamma, and observing it though a debugger ... if you can't, all you are is a waste of time to me ... indeed, to any of consequence in this debate.

Regards,
JS

BTW, it's a DIPLEXER (pronounced die plexer)if you want to work 2 seperate bands, a DUPLEXER is for working 2 frequencies on one band.

So which is it you are looking for, a 2M duplexer, or a 440 duplexer,
or one of each?

Frank, that is twice that you have mentioned dipoleas a comparison.
May I remind you again that for equilibrium purposes the radiator
must be a wavelength or multiple there of, assuming ofcourse we are
considering a single radiator
To talk of a "dipole" when considering my design is totally
unreasonable.

Yes. In the 1950's the USAF studied small antennas for the "new" Boeing 707's that they were buying as C-135/KC-135. I remember reading about it in one of the magazines of the time. They apparently were not entirely happy with the antenna that projected forward from the top of the stabilizer. They continued to employ a belly-mount trailing wire on some aircraft at least into the 1980's. (Good info hard to find.)

If all the money the Air Force could throw at a problem didn't come up with some magic, do we have a lot of hope???

Correct, that is why you measure in it's final environment and at
the source to the antenna.
Again JB let me state I am not a newby with respect to antennas and
are very much
aware of the circumstances that you point to which is why I measure
at the antenna feed point.......
...Same goes for any tuner arrangement I use which is also at the top
of the tower as well as a camera when needed

Hope for what? Magic? The tradeoffs inherent in electrically small antennas are well known, and each design requires intelligent application of that knowledge to come up with an antenna that's acceptable in size, form factor, and performance for that particular use. Many, many antennas now being designed and ones in common use are electrically small -- the ones in your car's remote control key fob, your Bluetooth USB dongle or cell phone earpiece, and embedded in RFID tags are just a very few examples. With the increasing use of wireless devices, the need for electrically small antennas has grown rapidly, and there are a number of good texts devoted to that specific topic. These texts contain a good treatment of the tradeoffs involved and useful ideas for designs using currently available technology and materials, but no new fundamental theory.

Advancements in the art will continue to come with intelligent and clever application of established theory by people who understand the theory and how to apply it, not from tinkerers who lack this knowledge and conjure their miracles by vague hand-waving and bad measurement.

Interesting. Near the bottom of Page 1, right column, the author states he doesn't want to try to support a full 23-foot vertical structure on his garage roof. Yeah -- me neither.

Would it still work if the "J" had an obtuse angle between the u-shaped stub and the half-wave radiating element? I'm thinking the stub section could lay on the garage roof and the radiating element could be elevated, being somewhat easier to support at 16.5 feet of height.

I have a nice 6m Field Day J-pole I made from 450-ohm ladder line and feed with 50-ohm coax. I will use it to test the concept and report back. I think 6 and 10 are close enough for this.

I am going to tell you, once and for all. I have tolerated your limited mind, I have overlooked your shortcomings, I have treated you like you belong ... you do not.

You have repaid this with being obnoxious, ignorant, short on anything relevant to the arguments, discussions, and debates here ...

You fall one brick short of a full load ... if you were going to demonstrate better, you would have done so by now ...

I really refrain from this, and save it to the last ... however, you have squarely requested it ... and I have granted it.

Be damned with what you have invoked ... and may it fulfill what you seem to desire ... if I am the only one to recognize this, then so be it.

Regards,
JS

However, now that I have expounded and embraced my utter disgust and disrespect for you, and so tarnished yourself, let me continue; you are one of the most ignorant men I have had the displeasure of encountering in this hobby!

You stand as very notable, but to degrees most men find despicable. You have, indeed, made yourself notable to me; I can only wish to fathom why you would have chosen such dark, questionable and detestable means to do so?

If your "good ole' buddies have a word to say for you, now would be the time ... I fear I feel like engaging all you like ...

YOUR IGNORANCE DOES NOT PASS MY SCRUTINY ... but then, that is what you wanted ... for what purpose? Perhaps you can enlighten?

Regards,
JS

note for qrp portable operation you can actually make the antenna field tunable. just strip the jacket off the coax far enough for the lowest frequency of interest and fold back the braid over itself. to tune a higher band just push the braid back up to cover the center conductor to shorten it to the new frequency. doing this a lot may wear out the braid, but for a temporary portable or emergency antenna it works just fine.

While you are correct, if you look in the catalogs you will see the devices
to split to two or more antennas on differant bands are listed as and called
duplexers. Diplexers are not mentioned at all. Just another case where
people started calling something it is not and the meaning seemed to be
changed.

Dear members,

Firsly i would like to apologise to all members if this message is being interpreted as spam. Frankly, i have no business connection what soever with the owner of shaamtfractal.com (refer to as shaamtfractal). I would like to appeal to any members who knew the owner of the site to contact me personally or through this discussion group.
I have being following shaamtfractal since i stumbled upon it 3 weeks ago from a search engine. It seems that the fractal pattern is quite unique in the sense that it doesn't match to any of the conventional formula known. I have failed to replicate it using any technique known (especially "Conflict Chamber 4", "Turning Point 2" and most of it in the gallery). I am looking from the academic's perspective and not from the artistic's perspective because to me color & shade could easily be manipulated using a wide range of graphic tools.
Some of my academic collegue gave an opinion that the image could probably being produced from a high-end graphic software but they are amazed when i showed them the enlarge original's image (7680 x 5760) because it exposed the very fine detail of the unique pattern not found in others fractal pattern. "Medussa Belt" clearly show a grow-like pattern.
I have tried in vain to get more details regarding the formula used from the site's owner but the reply is that it is an industrial secret. From Whois the site is originated from Malaysia (one of South East Asia economic tiger).
BTW, i am not trying to steal any formula from the site owner but just trying to get some clue regarding the formula & technique used to produce the said images and hoping that fractal theory could made a significant leap forward.

regards,
Fractal John Doe

It is a curious thread. You have made any number of very clear
propositions offering testable statements, and you can't supply the
least scintilla of evidence, example, case, illustration, instance,
representative, sample, or specimen in their support. Well maybe a
cupful of specimen where, no doubt, this last comment of yours runneth
over.

Brett, if your own statements lead you to such embraceable disgust
(what a concept), imagine how others perceive them. :-)

Wat I saw on their site is not very fractal, and not very appealing
either, compared to a lot of free sites i have seen lately.
And the amount of crossposting(or is it multyposting??) tells me
that a spam interpretation is quite likely to hit the target.

Yes Frank but you have to remember mine is a new design. The antenna
is now on the ground
and has a resistive impedance of three figures. I anticipate that when
I put it on my 30 foot tower the impedance will drop
on top band by 50% where I will add a transformer to drop it to 50
ohms. Now on the other bands it may well not need a transformer
so I can play around on 20 M for the winter until I can achieve a good
match or place a tuner at the tower top.
As I have stated many times a radiator does not have to be straight so
figures found with a dipole are just not applicable in my case.
In fact a anti resonant impedance can be driven below 50 ohms if one
wanted to so prior findings are just not applicable.
In a month or so you will be able to put my antenna on your computor
program and check for yourself I promise you.
Regards
Art

What's "fractal theory"? How does it differ from any other theories?

By "magic" I meant the development of technology that was heretofore
unidentified, not some false illusion by a conjurer. I agree with the
essential need for "clever application of established theory ... [etc]" as
you so eloquently stated.

In that sense, the IC was magic. (Sorry if I seem to liken technology too
much to magic.)

If the USAF crew all read the same books before their journey then
they all had the same experience many times over.
What it takes is imagination and the will to deviate from the well
trodden paths where different experiences and views
empower men to challenge the old based on experiences that others have
not travelled. It then takes a generation
for those that failed and snarled at the new to leave the scene so
that later research turns up the more recent past
and thus reinvents the wheel. Einstien left classical physics because
he could not find the key for the Universal laws
and probed into the science of relativity purely to gain a different
perspective or view of the former problem which required
a move away from the well trodden path to get the answer.
Unfortunately he died before finding the answer but was on the right
track
in not assuming that all was known because of the high number of

failures before him who all trod the same path and arrived at the same destination.

Or, to summarize, you would trash great minds in your personal pursuits to institute a personal attack ... now that it has been pointed out to you, blatantly, your vision has probably improved.

But then, one would have to look behind ones self, occasionally for that to be of use ... which brings to mind, "Fools rush in where brave men fear to tread." Or, something like that ...

Oh you noticed; for someone to have an intelligent conversation with you, you would first have to say something intelligent.

I tell you, I can't tell if there is real hope, still, for you, or not ... I won't tell you which way I am leaning, it might influence the outcome. ROFLOL

Anyway, you are always good for a laugh.

Anyway, as usual, you missed the point. The "silence" you are pointing out is the sound of everyone firing up their favorite antenna modeling software, such as MMANA-GAL, then realizing they are actually going to have to construct something to get complete data ...

However, I can almost hear your thoughts, don't bother stating them; I will state them for you, "Now how do you like that JS? I am your worst nightmare!" -- Just before the room fills with laughter ...

Voodoo science exists within the NEC code, the cat is out of the bag,
end of story ... of course, you are a "flat-earther", that changes
everything in your imaginary world ... and, due to near-sighted-vision,
will remain there, for you ...

Not only that, you now wish to take your imaginary vision into realms
where you are without grounds to go ... download the code, compile, link
and debug ... or else, get out yer' knitting needles and join the women
in the other room ...

Sorry Brett, gumming repetition does not prove an idea you already
allowed as being a dead and embraceable disgust. You clearly don't
have any idea how to progress beyond incantation of trolling
prosodies.

To your credit, no one expects originality from you. After all, that
is the point of your (self-supposed) anonymity (an ironic joke I
enjoy). You could as easily be Sara luxuriating in the flush of your
TV debate victory (complete with your aw-shucksisms)!

Presuming you're having troubles at HF, almost any aperture size will
do. (the usual guideline is that the perimeter of the aperture be
<<wavelength)

Of course, this only applies if it's an Efield issue. And, of course,
it assumes there's no conductors penetrating your "perforated box"
(which is what the shielding screen is). Any conductor penetrating the
box needs to have filters that "short" the unwanted signals to the
"inside" of the box.

If it's the radiated magnetic field, there's a whole 'nother set of
problems you'll have to deal with.

John, do me a favour and re read Richards last 5 or 10 posts and then
ask yourself
Did Richard provide any thing to you that was usefull? He will only
supply querstions
so that he can belittle those that try to answer. He himself will
never supply anything
that is seen as profitablke to this group at large. If the last 12
postings doesn't satisfy
you then look at the last 25, or 50 postings. There is no likely
hood that he is going to change
after spending several years taking this tack to annoy people on this
group. So why respond to him
which only satisfies his quest of being belonged as a person some
where in this World.
He is lonely, he is without friends and just an obnoxious person
seeking a conversation with anybody
and I mean anybody that he can rope in and annoy just to extend the
length of the conversation so he has a sense of belonging.
So John look at his past postings and ask yourself is any conversation
with Richard worth while and then take the appropiate action.
He can then turn to KB9RQZ to satisfy his needs without disruption to
the rest of us and where he will find a true friend with similar
tastes.
Best regard
Art

Can you believe that? This guy is claiming that the method of moments
is voodoo science! I wonder what is peek under the hood was. What
books did he read? Can he still read books? It's twight time...

That is true because the microwave portions of the spectrum is
becoming so pervasive. But not HF.

John could well be correct as certain assumed conditions(assumptions)
were set over and above Maxwell's laws
prior to the program being computed !
These programs are generally used to determine the functions of planar
antennas and the like that do NOT meet
the conditions implied in Maxwell's laws. One condition implicite in
all the laws of the masters is that
Newtons laws with respect to equilibrium must be observed, which rules
out such arrangements as the Yagi.
This is not to say that Maxwell's laws are used incorrectly in antenna
programs,only that it is usually used outside
its intended usage where acountability of all vectors are not
accounted for, which thus provides aproximations
Close enough for horse shoes and lemmings but not for the pursuit of
science along the lines intended by Newton and others.
Best regards
Art Unwin KB9MZ

Well, let me see here, I mean, I want to give you all due respect, and all that ...

Have you presented material since the 1960's for us to preview ... no, no it seems you have not ...

Have you presented any pertinent data which would catch ones interest, no, no you have not ...

Have you presented any antennas which cannot be found in 1960's or prior articles, papers or books, no, no you have not ...

Have, you presented ANY areas which have not been gone over 1000 times ... no, no you have not ....

Have you been a pain in the arse, demanding attention to your mutterings, claiming importance to your mutterings, well, yes, yes you have done that ... YOU HAVE DONE THAT, UNFORTUANTLY!

Other than the bedrock of antenna literature, what have you to offer? What do you have to say that we cannot find in a book by one of your favorite gurus? What new have you offered, since, like say 1960?

Richard, if you are going to invoke minds such as Cecils', such as Roys', such as Walters', such as many would were writing articles when I was an adolescent--could you not reach down and offer just a bit more ... I mean, if it is within your reach ... ROFLOL

No, no you cannot, however, surprise me ... it has happened before ... perhaps you have saved the best for last ... or, is all you have to offer more butt kissing of those who have gone before?

Sad, so very sad, but then, you already know that and have prostituted all your mental prowess getting here ... <imagine-a-tear-in-each-of-my-eyes>

May Heaven provide you with better ...

Regards,
JS

John,
I have not read anything over the last two years regarding the M.O.M / NEC
Can you give me a smigeon of information of what is being said of such programs?
There was mention of such in a ARRL compendium a few years back that made mention of the assumption made
on the continuity of an applied sine wave which conflicts I believe with the Tank Circuit equivalent.
And ofcourse some programs do better with respect to proximity effect better than others, but I have never seen anything of major content.
I do know that all four forces of the standard model are included in such programs however they are rarely utelised since they are not really understood
in the present state of the art.
Regards
Art

Art:

Actually, Roy, or one (or all the hams) engaged in writing an interface
to the NEC engine (MMANA-GAL and 'those guys' -- do an internet search,
their emails are readily available), which frees us from having to enter
the actual numerical data into a text file, would be much better gurus ...

As you know, I am much more interested it what we can't see, at the
moment -- the either ... Art, I have as many questions as you ...

Regards,
JS

3476. Seeking New FAQ/Intro Maintainers for rec.radio.amateur.*

Archive-name: radio/ham-radio/recruitment
Revision: 1.1 2007/09/29 18:42:47
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.
```

No you don't. This maudlin appeal is weak tea, save it for Authur who
shares your disability in lack of originality.

I do applaud the parade of the lame and lazy excuses you two manage to
bluff up in the guise of outrage. What a hoot! Insisting others to
prove your claims has to rank up there on the honor roll of welfare
queens. If the Congress had a bailout for ineptitude (and it has been
fairly proven they do), they would have granted you earmarks for your
mutual admiration society diary entries. You guys scribble out those
tear stained pages like they earn tax credits. Weep on! The election
cycle still has 30 days of promises to be made to the technically
indigent.

Would probably work with ladder-line, but not with coax.
You would be turning your antenna into an off-center-fed
dipole with a relatively high feedpoint impedance.

Yes, I know. It keeps me up at nights worrying about it.

About the politicians that is, they deserve better associations than
to antenna inventors; and at 12% approval, politicians have higher
validation. After all, they at least offer you a solution even if,
like antenna inventions, it doesn't work.

Can you imagine *we the people* telling our leaders to "fix it" and
our leaders asking us "How?"

Hmmmm, Maybe the happiness twins have something going!
How many here would react positively to a write-in campaign to elect

Still the same band, right? Try it; I think you'll find it works
well. Though it unbalances the leg length slightly, you probably
won't notice much difference between lengthening one leg or equally
lengthening both. It may be possible for you to try equally
lengthening both just to see, if you care.

Cheers,
Tom

As some of the longer term readers of this group might recall, the same or superior characteristics can be obtained by shrinking antennas by having their perimeters follow a random, rather than fractal, path. A random meander pattern submitted by Dr. Steve Best, who also wrote several IEEE papers on the subject, was shown to be superior to a fractal design in the quality factor criteria put forth by Chip in a "challenge" the latter publicized here some years ago (2000). Anyone interested is encouraged to go to http://eznec.com/misc/MI2/, read the 0Notes.txt file, and download and look at the various competing designs. The designs are in the form of EZNEC files, which can be viewed with any EZNEC program type including the demo.

But this doesn't explain what "fractal theory" is, unless it means the creation of antennas whose perimeters follow a fractal curve. In that case, "fractal theory" hasn't been shown to be superior to "random theory", and in some ways really no better than "square theory" or "round theory". Sounds a lot better when trying to talk potential investors into reaching for their wallets, though.

The Bird wattmeter won`t affect tuning and loading of an antenna if it is made part of a half-wavelength of line inserted for the measurement. This may be important at VHF and higher frequencies. The inserted line and its meter need to be specially tailored to make up a half wavelength, if it is to be inserted in nonflat lines. For several different frequencies, several line measurement assemblies are required.

Guess I need a tuner, then. A small piece of wire is more convenient,
but c'est la vie.

I'll cut the legs for the center of the range I will be using and keep
SWR low with a tuner.

I have no idea what "fractal theory" means. It's not a theory. It's a mathematical alogorithm with divisible self-similar properties that can be applied to antenna design.

Their web site seems to have been suspended for some reason.
<http://www.fractenna.com/>
is getting redirected to:
<http://ns4.netatlantic.com/suspended.page/>

Overview and references:
<http://en.wikipedia.org/wiki/Fractal_antenna>
Note that the article hints that a fractal antenna are intended to maximize the element lengths through self-similar repetative patterns. Whether a fractal (tubulence model) or a random meandering array is more effective is subject to some debate. Fractals may have a more efficient packing factor. (note: I don't pretend to know any more about fractal antennas than I've read).

That is exactly correct. The fractal antenna is an optimised meander
antenna where
the radiator "packing" per unit space is superior. It is just that a
fractal pattern has a
mathematical background where impedance can be garranteed where-as a
meander line design is subject
to human error. I see no reason why one antenna should be seen as
"better" than the other
if the radiating length and the unit areas are the same. I also see
this as another example where people talk down on this antenna
as a way of resisting change. Obviously industry see it as
particularly usefull especially with encapsulated designs and Chip is

making a lot of money
despite the dirisivenes of the "experts" on the newsgroup..

I may have been mistaken about your intent. Are you using
the above idea to extend your frequency range within a
single band? I earlier assumed you were going for multi-
band operation.

If you are expanding frequency coverage within a single
band, your idea should work just fine.

What band? What frequency range? How much space do you have? Numbers
are always helpful.

I dunno about an asymmetric dipole. I've never seen it done, which
makes me suspicious. It should be very easy to model to see what
happens. Numbers?

If you want bandwidth from an HF dipole, look into a cage or birdcage
antenna. It's especially effective at 160 and 75/80 meters. There's
no increase in gain over a dipole, but the usable bandwidth is much
better. Even better, is a biconical, which is a cage antenna where
all the wires come together at the feed point, and are spread into a
cone shape at the ends. You can get several decades of usable
bandwidth out of a biconical with a fairly constant gain. That's why
it's used for EMC/RFI testing:

Before we get too far off base here, Fractal theory does not refer to
fractal antennas. It is an entire field that might be characterized as
the science of self similarity.

Somehow I see Richard C. making a comparison any moment here in his
latest skirmish with a couple other posters..... ;^)

There are various tests for randomness.
<http://www.ciphersbyritter.com/RES/RANDTEST.HTM>
Random number generators are well developed.
<http://www.random.org>
I see no reason for "human error" unless you use a coin toss or dice
throw to design your antennas, which would be quite tedious.

> I see no reason why one antenna should be seen as
>"better" than the other
> if the radiating length and the unit areas are the same.

I do. Trying to shoe horn efficient radiators inside a small package,
such as a cell phone is not a trivial exercise. There are lots of
compromises that can be made if the design is constrained in size,
such as tolerating a high VSWR, strange pattern, and bandwidth
limitations. Incidentally, the primary limiting factor is size,
followed by SAR (specific absorption rate). Gain and pattern are
lesser priorities. VSWR is somewhere near the bottom.

>I also see
>this as another example where people talk down on this antenna
>as a way of resisting change.

Resisting is a complex problem, that includes imaginary parts. Any
reactance introduced into your change will convert your resistance
into an impedance. Think of it as people impeding change, not
resisting change.

>Obviously industry see it as

It works. You are not shifting the center point of the dipole
enough to really cause any problems as far as balance, etc.
I do it all the time with portable dipoles.

Ken,

If you design the antenna for a high frequency, and then start clipping, it will resonate at a higher frequency. No amount of clipping is going to give you low SWR at a lower frequency.

<<<<<>>>wanted to thank everyone for responding and offering some tips

just a few FYI's

I doubt i could afford or be allowed to build a 'cage' around the
entire room

The motor emits to noticable noise

the motor controller in the cabinet aka magnetek600 sure does.

i would be easy i guess since it's rather small um loaf of
bread sized to build a copper mesh around it i was considering
going to a a/c place and have them do it professionally

measuring w/my ft-817 and a small hand held spectrum analyzer i
measure almost no noise along the input power lines nor any
out to the motor there is 1 sensor cable to the motor also
no noise all are run in seperate conduit

best as i can measure that is

appreciate all the help folks

Hi Jeff,

You have quoted one of Art's more cryptic statements, especially when
he hasn't the vaguest notion of what a fractal antenna is and has
talked it down on many occasions when I suggested he visit a site with
more 300 pages of modeling and measured results:
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm

This stuff is over a decade to 15 years old, and possibly contains
(long) prior Art now found in (new) patents claiming to be original
work. ;-)

I worked out a general rule for fractal design, but it is of academic
interest only, and is distinguished in that role by its lack of
discussion here. ;-)

In fact, I can well imagine Art, in high dudgeon, would furiously
refuse to go there. I mention this only because that vaudevillian act
is so outrï¿½ as to be camp Art.

The test for this distinguished role follows from it being discussed
hereafter, or the language of this posting. :-0
(I vote for Artrï¿½.)

I think he is talking about clipping extra wire to one end, as with a clip lead, not clipping off a piece of existing wire. That would not be repeatable anyhow.

Hence, impractical for multiband use, where the sampling line might just as well be left in place and considered part of the whole line length even for those times when you have to insert a 5K watt slug (because your 500 watt amp pegs the 1000 watt slug) just so you can fully load for maximum forward voltage with your Pi-Net.

Certainly useful for your 2m antenna being fed with surplus CATV hardline so you can adjust the line length for a multiple and find a good SWR. But are there still reflections? Yes.

Here is the link to the assembly instructions of the AV-18AVQII.
http://www.hy-gain.com/man/pdf/AV-18AVQII.pdf

As the previous poster said it uses traps.

Maybe you meant the AV-18VS which uses the coil at the base.

I would be interested if someone has the details of the coil, diameter,
number of turns and the spacing and the wire diameter as well.

Here is the link to the AV -18VS assy instructions:
http://www.hy-gain.com/man/pdf/AV-18VS.pdf

Has anyone ever tried putting a dipole antenna up with the center insulator being a high power 50 ohm dummy load,then connecting the dipole elements across the dummy load.This would always keep a suitable match at 50 ohms and satisfy the transceiver.Would most of the power go to the dummy load and not the elements and wouldn't radiate.In thinking about this it all logically makes sense the load would really never change or would it have some reactance with the dipole elements.
Thanx All
Howard

Yes. There was a commercial antenna quite a few years ago that did just
that. I think QST did a review on it. It wasn't advertised as a resistor
across the end of the coax, but they either tore the thing apart or
X-rayed it, and there it was.

> This would always keep a suitable match at 50 ohms

I guess, But, and hold on to your hat... 50 ohms SWR is not an
indication that an antenna works at all, much less that it works well!

Imagine where the power is going to and what it is becoming. To the
resistor, and it is becoming heat. Anything that is radiated is almost
an accident.

Not a bad deal since you have to replace the connectors on the stupid ones you buy.

Looks like pretty good isolation too. Most off the shelf units are 45-60 db isolation. Double shielded pigtails eliminates any worry of cross coupling and the loss for one connector pair anyway. How does it do with 100w FM and long QSOs? Seems like SM throughout would be called for.

There was some phony antenna that when tested turned out to be nothing
but a resistor across the feed point. Google search and my fading
memory couldn't recall the name. The VSWR was great, but nothing else
about the antenna was useful, probably due to all your RF power being
dissipated in the 50 ohm load instead of being radiated by the
antenna.

A squashed rhombic with an approximately 500 ohm resistor does have
some proponents. See:
<http://www.hard-core-dx.com/nordicdx/antenna/wire/t2fd.html>
<http://www.hard-core-dx.com/nordicdx/antenna/wire/t2design.html>
<http://en.wikipedia.org/wiki/T2FD_Antenna>
Search Google for "T2FD antenna".

When you run a 73 ohm "resistor" and a 50 ohm resistor in parallel?

You would need a balun (rf transformer) to match to that antenna ...

Then you would need a suitable name for it. Let me see, we are mating
up a "dummy load" with a "dipole." How about "Dummy-Pole?" <grin>

This looks like a 160M antenna in 6 shoeboxes. At least at the start
of the page. By the end of the page it looks like a design from 80
years ago: the Beverage.

The page would benefit if it had a premise (prominently shown).

You could also use more definitions. A whole lot more.

Be careful of your usage of "balanced" as it may infringe upon the
current (no pun intended) usage of "equilibrium." That aside, this
page seems to be as readable as Art's distinctive writing.

As for the usage of:
" 'Cos seeing is believing!"
is that a dialect from Italy?

You would probably be better off loss-wise just using 1000'
of RG58 feedline......same result; lots of loss, low SWR.

Seeing is not believing. Or as Prez Reagan might have said "see, but
verify."

When I copied the photo "a demonstration of radiofluorescence" into
photoshop and reduce it to eight levels of brightness, the same cosine
shaped curve that is typically found in short antennas is visible.

The light is brighter by more power, it is not equally bright along
its length. The excess power is nearely saturating the camera's image
out to the end. Stop down the lens by 4 or 8 stops and publish that
picture - we don't need to see the patio furniture.

Been there, done that. About 30 years ago, I went on a field day
exercise where one of the HF stations was running a lightbulb on a
pole for an antenna. 100 watts RF, about 50ft of RG-8/u, voltage
stepped down with some kind of xfomer or balun, and a 150 watt
incandescent light bulb. I don't recall how well they did, but I
could see that the log was filling with contacts. Who needs an
antenna anyway?

Firstly, your proposal does not produce a 50 ohms antenna at all
frequencies. Your circuit analysis skills are lacking.

Various antennas include a resistance somewhere, and although it means
loss, it limits the feedline VSWR excursions with frequency and the loss in
the resistor may be more than offset by the reduction of feedline loss at
some frequencies.

Owen

Not so useful for most amateur applications, but very useful for what remains of professional HF radio. Frequency agility is often required, particularly by the military, and operators either don't have time, or skill, to fiddle with antenna tuners. Unless you are manpack portable, the loss of signal can be made up by increasing power.

Automatic antenna tuners are getting ever better, though. May be these designs are getting less popular.

hi

I have a few ham rigs that have a seperate rx antenna, if i
activate this function it simply choices this for rx when unkeyed.

my Yaesu mark v Field have 2 jacks for rx antenna marked in/out

so i am confused dson't seem to say anything in the manual about how
that actualy works

i suppose the IN would connect to my receive antenna but what would
the out connect to

A transmit/receive relay switch? I don't know either. Just a guess.

That is very similar to what the Maxcom Antenna Matcher
did. It was reviewed (and panned) in November 1984 QST.
As you suspected, almost all the power would go into the
dummy load and very little would be radiated.

Honestly, it's not a very good idea. :-)

"The motor emits lo noticable noise. The motor controller in the cabinet
aka Magnetek 600 sure does."

The cabinet should be made RF tight and grounded.

A brute force pi filter, series L and shunt C on every conductor
penetrating the shielded cabinet usually solves the interference.

Hi Myles,

My Drake TR7 has the same thing (a separate antenna jack). It also
has a switch. The switch goes to the T/R relay. In one position of
the switch, receive follows the transmit path and shares that antenna;
in the other position of the switch it goes to this second antenna
jack so the receive has a separate antenna and does not share with
transmit.

When all else fails, RTMFM (read the meticulously formatted manual).

<<seems i didn't explain the set up right

in the menus there is a switch to use the rx jacks

on the ts2000 it's 1 rx jack on or off

i understand this

on my markv Field there is also a rx on/off setting

but 2 jacks(not a switch) one is rx antenna INPUT one rx
antenna OUTPUT

i can guess what the input is for i plug my rx antenna there but
what is the outputfor?

i see a few righs now have that set up just can't think what
that is for

and it's not in the manual

these are rx only jacks, naturally the rigs have regular main
tx/rx pl259 jack

thanks

Sometimes when a station uses say a beverage antenna for separate receive, there will be multiple rigs using the same antenna. Take the antenna to the input, and the output goes to the next rig.

This one is meant to be a poor antenna, for use at really close distances.

http://www.wa0dx.org/wa0itp/dlspecial.html

Here is the gold standard, the MaxCom. If you gan get the link, QST had
a review. It was a toroid, and 3 resistors. Apparently a very high
quality dummy load (these things cost between 600 to 900 dollars!

http://www.eham.net/articles/14905

Had great SWR tho'!

Once I joke about using a CB groundplane with a 10 db pad for an all
band antenna.
I thought about this for a while and decided to try it. I did nt have
to use 10 db maybe it was only 3db or 6db I cant remember now
to get an antenna that my soliddtate transceiver with no tuner was
happy with on allHF bands. I was fairly amazed at how well the

antenna worked or at least amazed that it did work at all.

I would go to the page of the manual that shows the rear view of the radio,
with the various jacks numbered. It should state what each is for, and on
what page you can find more information. Are these RCA jacks? My guess about
the Rx out is that it might be for connecting to an external preamp.

A little weird but here goes:

Input to the A/B antenna inputs are TR switched to the RX via relay RL 1002.

If external RX antenna is selected in menu, the TR switched RX line from A/B antennas go to "RX out" rather than to the internal receivers while the "RX in" is switched to the internal receivers.

3548. Hygain rotor quality decline?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-10 05:36:10 UTC
From: ddl@danlan.*com
Message-ID: <1350382@news1.IPSWITCHS.CMM>
Source record: 21022
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

I just installed my third HAMIV rotor; I got about 4 years each from
the previous two. The most recent failure was the pot, with 5-6 turns
worn through at the spot I usually leave the rotor. Makes me think
the brake wasn't working very well. The previous unit was freewheeling;
I don't remember exactly what was wrong. The screws holding the case
together are always corroded in place so any repair becomes less trivial
as they break off. And anyway the inside usually looks bad enough (with
lots of rusted ball bearings) that repair is unappealing.

On the current (new) unit I noticed that one screw hole for the control cable
cover plate was stripped (and they should have noticed too since the screw
was hanging out) and one mounting screw hole was not tapped to full depth
(I had to get a shorter bolt).

I bought the first HAMIV about 8 years ago to replace a HAMM from the
60's (IIRC). They say the HAMIV is an improvement but it certainly
doesn't seem to last as long. Is there another rotor with the same
mounting pattern that might be better? It's an inside-tower mount
so I'm kind of constrained. Maybe I should look at rebuilding the HAMM?
It was seized but I still have it.

If anyone wants the two failed HAMIV rotors for parts let me know or
I will probably toss them soon...

Hello, and generally not if maximizing operating efficiency (the portion of available transmitter power that is being radiated by the antenna) is of concern. However, placing a low-loss pad between the output of one device and the input of another can be a simple, inexpensive broadband matching technique if the power loss in the pad can be tolerated .
Sincerely, and 73s from N4GGO,

The Mk5 Field radio is a mass of menus, and some of them will make the radio appear not to work. Technically it is a great radio, but I don't like it very much. Our club has one, and that means that those of us who don't have one have to re-learn it every time we use it. So if the manual is lost, so am I. Love that one punch notch filter though.

What is more, you didn't have to spend 600 dollars for a bad antenna.

But as a good operating practice, Hams usually want to have efficient
ways to transfer their limited power.

It's in that realm between extremes - the Person who never puts up an
antenna because nothing is perfect enough, and the person who is willing
to waste almost all their power in the name of Low SWR, or maximum
convenience.

IMO, it's best to settle somewhere towards the more efficient end of
that group.

Which I guess is why I have a big ungainly Bug-Catcher type antenna on
the car instead of a short and cute whip.

Hello, and you can have a physically short and efficient whip if you
choose an appropriate frequency band ;-). Now what ever happened to those
cute car-mount cell phone antennas? Guess they're in antenna heaven along
with the K40s. Sincerely,

I like my TS2000 for that reason. Gives me back 40 meters. Most of the
useful buttons are cloistered around the tuning knob. Great for one hand
operation in contests and events. Probably doesn't do all the MP field does
but great bang for the buck.

I was a station trustee for a club and wrote one page instructions with
short notes about quirks, to post or put in plastic. Just about any radio
is a problem for those who don't own one. I keep my TS130 for the GOTA
station. You would be astonished at how many radio techs would fix the
radio and have to break out a Op Manual to do a radio check. Even my own
radios, I keep the PDF shortcuts on the desk top.

The instructions say nothing about the RX out. You have to go to the
schematic.

Nope. The cell phone antenna on the vehicle roof has been replaced by
a GPS telematics antenna, GPS map antenna, wi-fi war driver antenna,
XM/Sirius DAB antenna, GPRS antenna, and possibly a mobile DTV
antenna. Aerodynamics and safety have dictated that today's vehicles
have curved roofs and air bags in the door columns, making most
permanent roof top antennas impossible. Besides, most of today's cell
phones do not include an external antenna connector or need a car kit
"docking station". Besides, modern cell phones have to handle a wide
variety of frequencies for world cellular coverage, GPS, wi-fi,
Bluegoof, mobile TV, WiMax, and whatever else can be crammed in. A
single external antenna just isn't going to work without a diplexer
and multiple connectors. At least the antennas are now all internal
or the typical smartphone will look like a porcupine antenna farm, or
if retractable, a Swiss army knife.

Incidentally, the K40 has been replaced by the Wilson 1000 and 5000 as
the mobild CB antenna of choice.
<http://www.wilsonantenna.com/w1000.htm>
<http://www.wilsonantenna.com/W5000.htm>
Good to 5,000 watts AM or 20,000 watts SSB. For mounting elsewhere on
the vehicle, there are antennas with oversized stainless base or
center loading coils that could probably survive a direct lightning
hit. Of course, you need two of them with a "co-phasing" harness.

That sure sounds like a short life for a rotator. As you have it inside the tower (?) I guess that you have a thrust bearing at the top of the tower. Are you near the salt water or in a very windy place ? Do you contes with it and turn it a lot ?

I put one up about a year ago that was used,but rebuilt. I am not in an area that is very hard on the rotators. I hope it will last longer than 4 years. It is in the tower about 5 feet down and I have a thrust bearing at the top. Just truning a 3 element tribander and beams for 6,2, and 432 on 15 foot booms.

Years ago, I was working on a Marine HF Radio, on the bench, in Seattle
WA, connected to a Bird 1 Kw Dummy Load. As I was setting the -16 db
Pilot Carrier Level for the Public Coast Station KMI, at Point Rayes CA,
on 12 Mhz, I got a reply from the Operator, ON Duty, asking for Station
Call Sign. I had a nice chat with him for about 5 minutes. ANY antenna,
no matter how it is built, even a Dummy Load, will radiate, and
communicate IF the Band is open. If the Band is closed, it doesn't
matter how efficient the antenna is, you will not communicate.

When using the radio with the padded antenna in a city environment and when utilizing nearby repeaters, it is quite acceptable to design equipment this way. It also reduces the sensitivity of the radio to unfortunate antenna shorts against automobile interiors or body parts.

If you have enough power left over to be DFQ into the repeaters with the power available, I see it as a viable compromise that can be most beneficial.

Hams tend to think in terms of operating simplex out into the far reaches of the aether, but there are many situations where padding is a useful feature.

Ed, NM2K

|
| That sure sounds like a short life for a rotator. As you have it inside the
| tower (?) I guess that you have a thrust bearing at the top of the tower.

There is a collar; I'm reluctant to elevate it by calling it a bearing but
it does prevent any significant mast bending moment from reaching the rotor.

| Are you near the salt water or in a very windy place ?

Yes, about a block from the ocean.

| Do you contes with
| it and turn it a lot ?

I don't turn it a lot and I always leave it in the same position since
that is the position that allows me to lower the tower and I wouldn't
want it stuck in some other position. Obviously this isn't great for
the pot if the brake isn't working well.

But none of this explains the reduction in life compared to the old HAMM
(I think we are talking nearly an order of magnitude) or the screw hole
tapping problems with the latest unit. Was there a stainless bearing
option (perhaps third-party) for the HAMM? That might have had something
to do with it. Other than the bearings (and of course the pot) the latest
failure doesn't look *too* bad inside.

Doesn't B&W do exactly that?

They called it a "balancing network" or some such thing...a resistor. Army published a paper on it in the 40's or 50's.

Problem is the loss it causes.

That is very disappointing and does not speak well for you.

I certainly expected you to realize a 1:1 balun (1:1 rf transformer
constructed in transmission line mode) IS a common mode choke ... :-(

Hang in there ... you'll get it ... eventually.

I must concur, here, akin to "Trickle Down Economics", we have the
"Trickle Down Transmission Line!" (or, TDTL) ROFLOL

Nope. I vaguely recall it was called a "lamptenna".

Somewhat later, I helped build a dipole using four 4ft fluorescent
tubes (two in each leg of the dipole hung horizontally on bamboo
poles). The 96" length was about right for a 10 meter dipole. About
80 watts out got the bulbs to light up. Once lit, the tubes were
quite conductive and made a functional transmit antenna and impressive
light show. It was totally useless for CW, kinda marginal for SSB,
and just great for AM. We had RTTY but couldn't find anyone to help
test it. We never did figure out how to light up the bulbs so we
could try receive. Various gross violations of the electrical code
and of common sense were attempted with no useful results.

There are those that can see the light...

Hello all. I am looking at building a half size rotatable 40M dipole. It will be approxiamately 10 metres long end to end. It will have a loading coil in each leg with about 5 metres of wire wound on a nylon former. My question is, where would be the best spot to mount the loading coils? Half way along each leg, ie- about 2.5 metres from the feed point or should the coils be mounted closer to the feed point? I realise that this antenna will be inferior to a full size dipole, but a half size one will fit where I am located.
Any constructive ideas or experience with loading coils would be appreciated.
Cheers
Max

the farther out you can get them the better it will usually work, adding capacitive loading hats on the ends of the elements will also help and increase the bandwidth.

Dan,
I think you may have answered one or two of your complaints. I
also think you have had a couple of 'manufacturing defects' that the
company really ought to fix.
Because of where you live, you are going to have corrosion problems
no matter who makes your rotor. About the only simple means of
reducing that corrosion problem is regular maintenance, more regular
than 'normal'?
Two 'duds' in a row is sort of unusual. That tends to tell me that
quality control may not be the 'best' in the woprld, or at least could
be a little better. I'm sure they won't jump for joy with another
complaint, but I certainly think I would complain if it were my rotor!
Good luck.

Dan,

Since you live so close to the ocean, you might want to try and coat (spray paint) the rotator assy with NEOPRENE PAINT. (This paint is waterproof & impervious to salt water & diesel fuel and you should be able to find it in either a well stocked hardware store or paint supply store).

You also might want to coat any open antenna connectors as well as any coaxial connectors.

Your other option would be to coat your rotator with a 2-part epoxy based paint, although this is rather expensive, and if you had to take the rotator apart it would be a BEAR OF A JOB! Personally, I would stay with the NEOPRENE!

Cheers
Max

the cushcraft 40-2cd and the xm-240 use them just after the loading coil.
They can also be mounted at the tip of the elements. They use two 18-24"
long aluminum rods in an X configuration. More rods, or adding a wire
around the tips adds more capacitance.

Where you place them is probably not too important to the performance but the inductance needed increases as you move away from the center. The center impedance will be lower than the nominal 72 ohms. EZNEC is good for evaluating the size of inductance and effect on center impedance. Reg, (SK) G4???, used to have programs, where you could plug in lengths and inductances and get answers about F and Z. I believe someone on this newsgroup archived his programs.

3581. Antenna ground or rig ground?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-12 03:12:20 UTC
From: Gary Pewitt <n9zsv@magtel.com>
Message-ID: <esp2f495cj16j0c1jmni43qrr7en6dp8fa@4ax.com>
Source record: 20955

Here's a simple question. I want to connect my transceiver to several antennas using 450 ohm ladder line and a balanced tuner. I found a couple of small double pole double throw knife switches for the ladder line. There are only two ways to hook these up. I can hook the tuner output to the center with the ground on the bottom and the antenna on the top connectors. This will allow me to connect the transceiver to the antenna or to ground. The second way is to connect the transceiver to the top contacts, the antenna to the center, and ground to the bottom contacts. This will let me connect the antenna to the radio or to ground. Is it better to ground the radio and let the antenna float? Or to ground the antenna and let the radio float?
Of course if I leave the switch handle sticking straight up nothing is connected to anything.
I am inclined to think grounding the antenna is better but I have been wrong before.

Thanks and 73 Gary N9ZSV

| > also think you have had a couple of 'manufacturing defects' that the
| > company really ought to fix.

Yeah, but somehow it didn't seem worth the bother. I was up on the tower when I discovered the short-tapped mounting hole and of course at that point it was easier to get a shorter bolt.

| > Because of where you live, you are going to have corrosion problems
| > no matter who makes your rotor.

Although the corrosion makes the rotors unappealing to work on I don't think it was the cause of the failures.

| > About the only simple means of
| > reducing that corrosion problem is regular maintenance, more regular
| > than 'normal'?

Perhaps, though I still wonder why the HAMM faired so much better. In order to do any kind of regular maintenance I think I'd have to replace the bolts that hold the case together with stainless in advance since they rust in place very quickly.

| > Two 'duds' in a row is sort of unusual.

Three duds...

| > That tends to tell me that
| > quality control may not be the 'best' in the woprld, or at least could
| > be a little better. I'm sure they won't jump for joy with another
| > complaint, but I certainly think I would complain if it were my rotor!

Yeah, again it just doesn't seem too productive. I'm sure they would be happy to have me ship back the latest one and I could wait around for a replacement with my tower down. (I put it up today.) I think I'd rather look for an alternative product or revisit the HAMM which I still have.

| Dan,
|

| Since you live so close to the ocean, you might want to try and coat (spray
| paint) the rotator assy with NEOPRENE PAINT. (This paint is waterproof &
| impervious to salt water & diesel fuel and you should be able to find it in
| either a well stocked hardware store or paint supply store).

I'm not sure how this would help in more than a cosmetic way. You understand that the rotor is not sealed, right? There is a gap between the bottom of the bell and the mounting plate. It points down so water shouldn't be *flowing* in, but the insides are certainly exposed to the weather. The only thing keeping the bearings from rusting is the grease, and the retainer strip really can't insure that they are always fully coated. The more I think about this the more I remember stainless bearings in the HAMM, though it might have been an after-market modification.

| You also might want to coat any open antenna connectors as well as any
| coaxial connectors.

I've had good luck with a tight spiral wrap of ordinary vinyl tape. Just took apart some connectors that had been up for more than a decade and they were shiny as new. Lately I've also been filling the insides with STUFF dielectric paste but I'm not sure this makes much difference.

Gary,
The biggest problem would be in trying to use the radio without connecting an antenna to it. If you can be sure of always doing that, then I would ground the unused antenna (personal preference, radio is grounded anyway). Same thing if you ground the radio's antenna connection. If you forget, it causes problems, sometimes big ones. I tend to make allowances for my bad memory. You may not have that problem, so...

Dan,
There's no 'fool proof' way of 'fixing' any rotor that doesn't mean a lot of inconvenience in some way. Picking the most palatable inconvenience is the 'trick'.
"Productive"? Uh, yeah, I agree with you, probably not very productive, But I'd do that complaining anyway. Who knows, they might really surprise you (and me :)).
Which solution is the best? I have no idea.
- 'Doc

Beat the @#$ thing to death with a very large hammer. Productive? No, but @#$ sure satisfying!

Hi Gary,

I see your problem right here.

There are four ways to hook these up.

Howdy,

In the 70's I worked on a project developing dual use small
boat radar. We had a terrible time with bearing corrosion at
first.

You might want to try wash-out resistant grease intended for
boat trailer wheel hubs.

In the radar we eventually used Andok C which is no longer
manufactured. Nye developed Rheolube 374C as a replacement
for Andok C. Both are an NLGI Grade 4 grease,

McMaster-Carr has a good selection of stainless steel bearings
and they have ceramic balls for bearings I believe. I'd want
to play with those a bit first before putting them up on a
tower.

73,
Grumpy

Yep, Johnny "little boi" Smith has an affliction for coat hangers. He recalls clearly like it happened just yesterday, on having to always evade a coat hanger that used to infilitrate his mommas pussy in an attempt to rid her womb of what was to become Johnny "Little boi Lover" Smith out of California. O bet that old caot hanger was also found on the freeway by his momma in her vain attempt. No wonder after spawning Johnny Boi she gave up on screwing and took up the art of blow jobs, which I hear she has no equal, other than her boi John Smith.

Good advice.

Most folks instantly think of stainless steels for corrosion protection. However SS is not a particularly corrosion resistant material around salt water. All commonly available grades of SS are subject to halogen corrosion, i.e. chlorides in sea water. Before retirement I worked at Eastman Chemical company in their research laboratories. They frequently had to resort to rather exotic alloys, such as Hastelloy C-276, for applications where halogens were involved. These alloys tend to be extremely expensive and nearly impossible to machine.

I would suggest using lots of a good grease and frequent maintenance if your rotor is exposed to salt air.

Go back to sleep, Brett. You certainly added nothing.

Switch one center posts: Rig - now called the rig switch
Switch two center posts: Antenna - now called the antenna switch

Rig switch position 1: both sides to ground
Rig switch position 2: both sides to antenna switch position 1
Antenna switch position 1: both sides to rig switch position2
Antenna switch position 2: both sides to ground

Rig can be
1. open
2. grounded
3. to switched antenna

Antenna can be
1. open
2. grounded
3. to switched rig

Both rig and antenna can be independantly open or grounded, or
interconnected. No real advantage in the open positions, but they are
available as a 6 state solution. As such, a 4 state solution that was
sought.

More switches, more states. Classic cross-point switching.

But we shouldn't have to spend 600 dollars to find that out! ;^)

While it is true that at ceratin times, anything will "get out", and at other times, nothing does, there is a whole range in between. I did some mobile contesting this weekend, and the consequences of having a bit more efficent and productive antenna were apparent. Mor QSO's, and less time spent doing multiple exchange sends.

And wow, the bands were weird this past weekend.

But given the results of shootouts, it is clear that having a good mobile antenna will add quite a bit of punch to your signal. IIRC the Hamsticks were about 20 db down (Cecil, I think you had some test results, so correct me if I'm way off).

1/2 to appx 3/4 out from the center point is usually about the best
compromise.
You want to improve the current distribution, but at the same time
not get so carried away that the loss from the extra number of
coil turns needed outweigh that.
With no hat, 3/4 the way out is about as far as you want to go.
You could probably go a bit farther out if you use a hat on each
end. But myself, I'd probably still leave it at about 3/4 the way
out even with a hat. The typical hats used will not be too big
vs the wavelength on 40m.. IE: Four spokes of 3-4 feet long
is not a huge increase in capacitance for that band.
So I would not run the coil all the way at the end.
Reg Edwards old "vertload" program will let you see the best
point to mount the coil, but it does not deal with hats.
Only a single "stinger" whip. It will also tell you about
how many turns for the coil at the various positions.
Those programs are probably archived on some site.
A google search would probably turn them up.

> around the tips adds more capacitance.

The tips is a better location for the hats. You get some degradation
if you
mount the hat just above the coil.
You can check W8JI's mobile antenna info for the why's..
BTW, you generally will use the same techniques for these as you
would a mobile whip..
A half size dipole is basically just two mobile whips end to end to
make a
dipole. All the techniques used to maximize mobile antenna performance
can be applied to half size, or smaller dipoles.

> 3. to switched rig

As a refinement I'd put a dummy load on switch #1 so that the choices would be:
Rig can be:
1. Open
2. To dummy load
3. To switched antenna

The antenna switch would remain the same -- open, grounded or to switched rig.

I'd rather run my rig into a somewhat reasonable load rather than a short to ground during the inevitable instance of forgetting to set the switch properly.

If running less than say 200 watts output then one could even use an incandescent light bulb for the dummy load. It would presumably light up if one were to inadvertently transmit in that configuration. So, the rig would be at least partially protected and the operator would have some indication of why no one is answering his CQ. Maybe a *red* light bulb?

One could also physically (not electrically) parallel the switches so there were only two configurations. The rig connected to the antenna =OR= the rig connected to the dummy and the antenna connected to ground. That would be cool.

3601. Measurements for a CDMA450 coaxial dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-13 21:20:56 UTC
From: jonaslonnroth@gmail.com
Message-ID: <c9baa1b0-2d86-477f-9ffb-5cca2759ccbc@u57g2000hsf.googlegroups.com>
Source record: 20975

I would like to experiment with a few different antennas to be used with a CDMA450 usb modem for portable use. The design frequency would be 455 MHz (second TX carrier of Scandinavian NMT-CDMA450). Boomer cells are now being introduced allowing for ranges beyond 62 km (up to 120).

The first design would be a coaxial dipole, i.e. with a tubular sleve covering the cable below the quarter wave tip. The design could be for RG58 with 0.66 velocity factor. From various sites I've seen a velocity factor estimate of 0.95 for the sleeve but no discussion on the diamter vs width of the sleeve. Also, I'm not sure that the sleeve should be an exact quarter wavelength. Reading the Franklin antenna Patent introduces a whole bunch of variables but for UHF use, the design should be well known.

I'd like to connect to the antenna with a TMC or SMA connector.

The tip would be a bare wire protected by a ball pen housing or the like.

Would using a ferrite ring on the cable below the sleeve help any?

I could compare this antenna to some commercial end fed half wavelegth antennas that I already have. I found a coaxial dipole to be a very good antenna on top of a 4 meter fishing rod 20 years ago when NMT 900 was started up and base stations few.

Regards

Jonas

3603. Design measurements for a multielement vertical NMT-CDMA450 antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-13 22:37:18 UTC
From: jonaslonnroth@gmail.com
Message-ID: <fbdbbc9c-f4d0-404e-b6c7-c0d5672b04f0@m74g2000hsh.googlegroups.com>
Source record: 20977

The multisection Franklin antenna for UHF has been widely published on the web. The first design is by N9ZIA:

http://www.qsl.net/n9zia/wireless/col432/index.html

This antenna used ground plane radials for decoupling

A modification by N1HFX uses a sleeve and ferrite toroids for decoupling:

www.rason.org/Projects/collant/collant.htm

There is also a design proposed by WA6SVT with a few variations in which a tubular sleeve is used and the coax elements covered with cupper tubes:

http://www.repeater-builder.com/antenna/n1bug-construction.html

I would like to build a pair of vertical multielement antennas for mobile use (when standing still) use to be used in cdma450 cell fringe zones. 7-9 dB gain should be enough to reach base stations of the outskirts of cells.

I suppose that a combination of the principles outlined in the articles by N1HFX and the ones cited around the WA6SVT design should work. Any feedback would be appreciated.

Q: How come coils are not used to space half-wave elements from each other? In several wifi designs, single loop coils are used. In some, coils consist of several turns:

http://mobileaccess.de/wlan/download/arlx-om2400-all-inst.pdf

So, what size should a phasing coil be for 455 MHz?

If you have a real problem with lightning in your area, do some reading on the situation. You might drastically redesign your grounding situation. The grounding should be tied together at the service entrance, so the antenna entrance should be near there and all tied together with low resistance to ground. This means the tuner should be there too or at the antenna The radio should be grounded to the entrance also. It is important that all grounding should be done outside the building rather than through the floor. That would bring the major current of a strike through your house. There are ARRL tis documents on the subject and a bunch of others.

Hi Jonas

It isnt made clear that this colinear array of 1/ wave diplies is quite sensitive to ferquency change and intolerant to construction errors. If you ask questions like "what size should the phasing coils be", you find some difficulty in getting a long array to work. I'd advise you to try one of the designs that doesnt use "phasing coils" and just try whatever is easy for you to build.
I have (in the 1960s) designed and manufactured antennas using this end fed concept. The radiation pattern is effected by frequency change. The beam max will squint up with higher ferquencies and downward with lower frequencies.

You will also want to dispense with the switches and use lightning arresters
so you won't be hanging onto several thousand volts built up on the switch.

Hi Jonas,

The links you provide offer nothing new on the subject. They are
appealing and thorough, but I notice none of them give any verified
data as to the operation characteristics (unless they are buried as
generalities within the text).

One very telling problem is that the popular method of using coaxial
sections swapping phase ignore that there are TWO measures of velocity
factor, and only ONE is being used to construct the antenna. The
interior section will NOT have the same wavelength dimension as its
exterior.

Another telling problem is that with the last link, there is ever so
much goop being added, and coils being wrapped that this MUST shift
frequencies and shifts by an unknown amount. As none of these links
offers measured characteristics, it is equal to building model train
sections for appearance's sake.

The original Franklin antenna used wire sections. You could easier
just bend one continuous wire into the appropriate shape and be done
with it. No issues of varying velocity factor, no phasing coils, no
problems of goop or wrapping tape, and you could use the same radome.
Open a commercial unit and you will find that is how the Pro's do it.

Hi Richard

The the antenna I designed for "ACI" was a coaxial construction I left
the "skirt stubs" without dielectric so the radiators were close to 1/2
wave long since the Vp of the coax line inside was also air dielectric.
The only good thing about the array antenna project was that the customer
was happy. Also, I did learn alot while developing the array. The one
thing I remember is that there is alot of beam squint with frequency

variation when the number of elements is high. I dont expect the array of the 8 or 10 alternating coaxes to be controlable in either VSWR nor beam squint. But, it might be fun to try building one and try it.

Jerry

Message-ID: <Xns9B37E2BFF7B46Huckleberrybigvalley@198.186.192.196>
Source record: 20984

I know this is slightly off topic, but since I am intending to run some RF cable in the conduit, and since there are a lot of intelligent hams on this group, I will proceed anyway:

Last year at the beginning of construction of a new house I buried about 50 feet of 3/4" Sched. 40 PVD between the house and a location on the property perimeter. Now that I am ready to use it, I can not locate the perimeter end.... it is somewhere in about a 10' area, and the end curves up to probably about a foot underground.

The ground is nearly pure sand, and is well landscaped now to the point that I do not want to randomly dig it up.

The end terminated in an elbow curving up and is well duct taped shut.

Can anyone suggest a method or equipment I might use to locate that far end?

Tnx.

Ed;

Run a metal snake into the conduit then get a metal detector and sweep
the area for the conduit. If this doesn't work there are wire tracing
detectors that might do the job. You hook the transmitter to the snake
and sweep with the detector.
If all fails you might try a metal probe. Stick the probe into the
ground and feel for the conduit. Or dig up a couple of feet of conduit.
Note the direction it is going then move in that direction and dig a
small trench where you thing the conduit is.
One of these methods should work.
If all fails install new conduit.

A suggestion for other folks who will be burying a conduit: Take a bunch of pictures before the trench is filled. It's good to include distances to some fixed reference points -- you can write them with a marker on big pieces of paper laid on the ground to get them in the picture. I haven't yet used the pictures I took of mine, but I sure have made a lot of use of the pictures I took of the uncovered walls of a home addition, showing the locations of all the studs and wiring.

Source record: 20991

Hello.. I am interested in modeling with 4nec2 a two element W8jk for
40 meters and higher frequencies. I was thinking of using two
elements similar to the rotatable dipole described at
http://www.k6if.com/40dip/40dip.html which uses capacitance loading at
the ends of a 40' element.
I have seen how to add loading in the form of a specified capacitance
in 4nec2 but am not sure
if it is possible to just physically model the capacitance hat as if
it were just additional wire segments. Any advice would be
appreciated. I had some fun with a "bamboo beam" made
in a W8jk design with two 24' elements spaced 8' and mounted up
20' (using #10 alum. wire).
Thanks in advance for comments... Whiskey5

Ive done this to locate wires in walls, might work for wires in
ground.

Make a buzzer form a relay by attaching the NC contacts in series with
the coil and battery.
Connect it to a wire running through the conduit making sure the wire
is not connected to power. The buzzer will generate enough hash you
can pick it up on a pocket AM rx.

If there is a wire in the conduit, just rent a "cable finder" from the
local rental yard. It's a low frequency transmitter and receiver
combination. If you have access to one end of the pipe, just shove a
metal "snake" into the pipe to provide a suitable conductor.

> The ground is nearly pure sand, and is well landscaped now to the
>point that I do not want to randomly dig it up.

That should be easy. Dry sand doesn't attenuate the signal much. Wet
sand is another story.

> The end terminated in an elbow curving up and is well duct taped
>shut.

Ummm... I think you'll find that the duct tape has dried out by now
and that your pipe is full of water and sand.

> Can anyone suggest a method or equipment I might use to locate that
>far end?

The cable finder is the right way. Ground penetrating radar will work
but is messy.

You can pressurize the conduit with an air compressor. That should
blow off what remains of the duct tape. Use your ears or a
stethescope to listen for the noise through the sand. If the end is
just below the surface, it should make a nice blow hole. Be prepared
to clean the sand out of your uncleable buried elbow.

If you think the pipe is clear, drop a small loudspeaker down the
other end and play rock music with a heavy bass beat. You should be
able hear that 50ft away. Use a stethescope.

It is certainly possible and is important that the top
hat wires be symmetrical around the connection point.
Whatever 'N' number of top-hat radials are modeled, the
spacing should be 360deg/N. It is easiest to model top-hat
radials in powers of 2, i.e. 4, 8, 16, ...

There's really no difference between elevated ground
plane radials and top-hat radials.

The only way to model the capacitance hat is as additional wires.

The W8JK presents a low feedpoint resistance, and shortening and loading the elements will lower it further. This will increase the potential for loss, so you might consider including the wire resistivity in your model. Also, the impedance of a W8JK changes rapidly with frequency, and shortening and loading the elements will further narrow its bandwidth. However, loss and bandwidth might be acceptable for your purpose, and capacitive end loading won't cause as much increase in loss and decrease in bandwidth as inductive loading would.

Thanks all for the input.

I agree, making that multielement antenna without any means for measurements is taking a risk that it will be quite inferior to a pro antenna and thus a waste of time. I found coaxial multielement antennas at procomm.dk. Length is between 70 cm to 535 cm.

So I back down to a hopefully more humble project. That would be taking a commercial mobile antenna wip of a 1/4 WL plus !/2 WL (Smarteq.com). It has a phasing coil inbetween. There is a side mount with a coaxial FME connector which could be used for a coaxial antenna with a quarterwave sleeve. The protruding wing (stopper) of the side mount would be taken off. It is then posible to slide a 1/4 WL Cu tube over the antenna mount. By fastening the tube to mount ground, one would obtain the sleeve needed for a coaxial exended antenna. Gain of the whip in a ground palne confguration is 3 dB.

Should a sleeve +protruding part of mount be eaxtly a quarter wavelength long at a velocity factor of 1 - or 0.95 ?

Damn ! NOW you tell me ! :^)

actually, I did take a gazillion pictures of the house construction
and from foundation, through all framing, to completion... but I
neglected the outside !

That's an excellent idea.... but I really hate water in my electrical conduits.... I'll use that as a last resort. Thanks.

A definate consideration.... since the ground is sand. If the
antenna rod doesn't just bend around the conduit... may just work. Tnx.

Dave, your idea above, plus some comments from others has made me realize that this is the way I should proceed, for my first attempt. I do have a Service Monitor. I'll simply run my snake into the empty pvc conduit until it hits the end (duct tape) and connect an RF signal to it, then using a small HT, track the signal down to the end.

My thanks to all for other ideas presented here, too.

Hi Ed

Have you considered the use of a wad of towel pulled thru the conduit to
dry it after using water to locate the burried end?

Compressed air could be used in place of the water. The air excaping
from the burried end shouild be easily detected.

When in doubt, couple ways the Pros do it:

1) Run a Metalic Snake thru it, and hook to a (Low Power RF , or a
Fairly high power A.F. source-- follow the snake (above ground with
an inductive sampler (or rf receiver)) to the end - use a cable
marker (Paint) to follow the duct if needed to find an intermediate
point , then repeat agan if necessary.

2) for those that have access to a "THUMPER", can do the same
Apply high level of sound to the PVC, and use a listening device
to follow the noise, in the ground.

Works for locating buried cables for utilities- should work for you!

Message-ID: <YixJk.1387$r_3.565@nwrddc02.gnilink.net>
Source record: 20853

How do the small low profile omni mobile for VHF
and UHF compare in performance to conventional
1/4 wave (VHF) and 3 dB gain (UHF) antennas? I
have a hard time believing they are anything
close to comparable.

Antennex sells a VHF unity gain model
(TRABT-1420) and a UHF 3 dB gain model
(TRAB-4303). They also hold a patent on 'field
diverse' antenna technology.
http://www.antenex.com/pdfsandzips/megwhitepaper.pdf

I know these antennas are very popular for
public safety applications - does anyone have
real world A:B comparison data comparing them
with a conventional mobile antenna?

Thanks and 73,

Tad Danley, K3TD

[snip]

Your thinking is quite correct. I've got one of their wiz bang "Mean
Effective Gain" rated antennas around here somewhere.

When I measured that antenna mounted top dead center on a vehicle the
performance was substantially worse when compared with a ï¿½-wavelength
mounted on the same vehicle.

I use a 4-wire cage inverted vee on 80m. With it cut a bit long (1:1 at
around 3650 KHz), it's barely 2:1 at 4000KHz. Spreaders are 1/2" thinwall
PVC... 24"x24". I used the handy design program at http://www.smeter.net/.

What an interesting thread!

How about one of those 'stage' smoke machines pumped into the open end?

Another simple way - the old Native American waiting for a train
method. Push the fish tape all the way until it stops. Person 1 keeps
ramming the fish tape and person 2 puts ear to ground near far end and
listens for it. Needs no batteries or smoke.

Nix the water. I like the compressed air trick, Just don't look
directly at the conduit end . .

That's a good one, too, but in my case, I KNOW that I duct taped the end of the conduit in such a manner that it is truly air tight... even possibly under pressure. Thanks anyway.

Well, how about combining the two methods? Find some flex lawn drip
irrigation tubing. Attach a bosons whistle to the end and shove it
through the pipe. Add compressed air and it should scream like a
banshee. That should be easy to hear through the sand. Maybe the
duct tape will act as a diaphragm.

Ed;

Thanks for the compliment. I wish you luck and envy you for your acreage
for antenna's. My lot here in St. Louis is something like 40 feet by
120 feet with the house in the center. I do have some trees along the
back alley that I have wire hanging from. Works but not optimal.
Let us know how everything works out.

Dave WD9BDZ

Check out a 1/2 wave DLM shortened to about 3/16 ... good performance
and small size ... you can get smaller, but performance will decline.

Beats catching bugs! (or, a Texas Bug Catcher!)

>denny/ k8do

Ummm.... this is through 3/4" schedule 40 PVC with at least two right
angles. The augers I've seen are for much larger sewer drain pipe and
will not fit inside 3/4" PVC. Anything that can drill through sand
can probably also do some real damage to the PVC. A much smaller
diameter "snake" is probably safer. With only 1ft of sand to push
through, a solid "tape" type electricians snake can be pushed through
by hand. The only down side is that the pipe will fill with sand when
the duct tape is breached, so cleanup may be a problem. If dry sand,
a small hose on the end of a vacuum cleaner should work.

Incidentally, the frequencies used by commerical cable finders are
815Hz, 8Khz, and 82KHz at 2-3 watts.
<http://www.rycominstruments.com/3-8879-Cable-Utility-Locator.asp>
However, that's good for 15 ft depth and many miles of cable. Higher
frequencies will probably work for 1ft of sand and only 100ft of wire.

Ouch! Unless you are trying to fish a phone line, you (might/might not/want) WILL dig it all up and go to 2" with 45 degree bends and bevel the inside edges. Once above ground you can break out to pull boxes.

You have my sympathy.

Hi Ed

Will the taped end will not leak with 80 PSI air in the conduit?

3647. Question on SWR

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-16 19:00:33 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <48f78f3a$0$40314$4fafbaef@reader5.news.tin.it>
Source record: 20871

I make here reference to the well-known chart, shown in almost all the ARRL Antenna Handbooks, setting the relationship among the real SWR (i.e. that measured at antenna), the SWR measured at transmitter and the "line loss".

In the text they explain that the "line loss" to be considered when using the chart is the line loss under matched conditions (i.e. that given by the line manufacturer), that is without taking into account the extra loss caused by SWR.

They make the example of a line having a (matched) loss of 1.0dB with an SWR of 4.5 at antenna. The graph shows that the corresponding SWR at transmitter is 3.0.

Unless I am wrong, a simple calculation shows that, in the considered example, the SWR at transmitter is about 2.3 rather than 3.0.

Here it goes (please note that, for the assumed SWR at antenna of 4.5, the extra loss caused by SWR is just 1.0dB):

- actual loss on the forward wave: 1.0dB (matched) + 1.0dB (extra by SWR), for a total of 2.0dB
- return loss corresponding to an SWR at antenna of 4.5: 4.0dB
- actual loss on the reflected wave: 1.0dB (matched) + 1.0dB (extra by SWR), for a total of 2.0dB
- return loss at transmitter: 8.0dB
- SWR measured at transmitter (corresponding to a return loss of 8.0dB): about 2.3

It is interesting to note that the chart would give an identical result if by "line loss" they would mean the total line loss (that is also including the extra loss due to SWR) rather than just the matched line loss (as they state in the text).

Any comment?

Thanks and 73

>You have my sympathy.

Thanks for the sympathy but it's not my conduit or problem. The
plumbing belongs to Ed, K6AAT.

Question: What's the difference between conduit and plumbing?
Answer: Plumbing holds water. Otherwise, they're the same.

I'm not sure what might be going inside a 3/4" conduit, but if it's
for a tower, it's way too small. The original question does not
indicate what manner of wiring goes inside. With 3/4", you can get
perhaps one run of LMR400 plus some flat rotator cable and you're
full. Hard to tell from here.

It's also possible to place a diplexer (or triplexer) at both ends of
the single coax run for splitting out HF, VHF, and UHF. I've done
that when running multiple coax cables was impossible.
<http://www.rfparts.com/diamond/Product_Catalog/plexers.html>

It's been a long time since I've done any tower construction, but for
commercial installs, I never used buried coax runs. AC power for the
tower lights were in 3" steel threaded conduit (not EMT), but the coax
was all above ground. That shortened the coax runs about 25ft which
was well worth the effort.

Incidentally, a good trick is to *NOT* lay the conduit perfectly
horizontally plumb. Put one end lower than the other so that water
well drain into that end. Shove a PEX sprinkler line down to the low
point of pipe and pump out the water once a year. I prefer
pressurized conduit, but a water sump works fairly well.

I discovered, the hard way, why using steel pipe instead of PVC was a
good idea. With everything underground, the obvious parking location
for the crane, cherry picker, or propane truck was directly on top of
the buried PVC. After a few cracked pipes, I decided that steel was a
good idea.

I like to pressurize the conduit slightly to keep the water out. It's really not necessary as most coax will survive when immersed. However, everyone re-uses coax, which has cuts in the outer jacket, and which might not be fully waterproof. A pressure gauge, bicycle valve, bicycle pump, some putty, and a few PSI are good enough.

I almost forgot.... a slow death to the installer that shoved a coax barrel splice down a stuffed conduit, thus insuring that all subsequent coax runs will jam up against the coax connectors.

Also, this is what happens when a monopole tower is stuffed full of coax cables, and some idiot decides to enlarge the hole with a cutting torch.

Well, if it does leak, the sand above the duct tape will dribble down
into the 3/4" conduit creating a rather awkward clean up exercise.
That's why conduit runs usually terminate above the ground, not below.
The trick is to find the conduit end without blowing off the seal.

I realized my error!

In my budget I counted the extra line loss caused by SWR twice:

- first time when I have added 1 dB to the loss of the forward and the return wave

- second time when I took some power out of the antenna (to account for an SWR of 4.5) and delivered it back to the transmitter

ARRL is always correct!

Sorry for the useless noise

Hi Jeff

It may be of little interest to the OP, but the sand might have difficulty leaking back into a conduit with air blowing out of it. In addition, the air might leak from a small rupture below the oipen end of the conduit. The OP may have no access to compressed air anyway.

Jerry KD6JDJ

Welcome to rec.radio.amateur.antenna.physics

Ok, let's do the math. Dry sand weighs 100 lb/cubic-foot. There's
about 1 ft of sand above the end of the 3/4" conduit. The weight
action is roughly conical, so the volume of sand involved is (my
guess) about:
100 lbs/ft^3 * 1/3 = 33 lbs of sand.
All that it acting on a 3/4" diameter pipe, with a cross sectional
area of about:
Pi * 0.75" = 2.4 in^2
Therefore, the pressure exerted by the sand is:
33 lbs / 2.4 in^2 = 14 PSI
So, if he can pressurize the pipe to more than 14 PSI, he can lift the
column of sand sufficiently to keep it from dribbling into the pipe.

Of course, it's not that simple. Laminar air flow, pressure gradients
across the conduit, and the effects of the duct tape will ruin my
simplistic guesswork. Worse, the back pressure created by the
immovable column of sand will force some sand particles into the
conduit around the edges with the "reflected" air pressure. In the
middle of the conduit, the air flow is all out of the conduit, but

near the edges, it could easily be the other direction. I'm also assuming that the sand is a perfect air seal, which it's not. To prevent all this from happening, the minimum air pressure should be about twice the 14 PSI, which is easily achievable with an air compressor, but not a vacuum cleaner.

I'm also trying to imagine how the process will work. I see an air compressor pumping madly away as the neighbors kids furiously dig around the resultant sand volcano, as sand rapidly refills the conical hole. In my never humble opinion, there's no way to prevent sand from dropping into the conduit if the duct tape seal is broken before excavating the end of the conduit.

Once the sand is in the conduit, just blowing air through the pipe isn't going to magically elevate the sand particles 1ft or more in the air. The air does not have sufficient mass to convey enough momentum to move the sand particles, much less eject them vertically. For that, one needs a denser medium, such as water. Shoving a plunger through might work, but it's equally likely to jam sand particles into the PVC conduit walls.

H E R E S Y

Reflected waves do NOT have power in them - or so goes the catechism.

This new and dangerous introduction of a side topic can only lead to
endless debate about the superposition phase properties of sand in
vacua (particel theories inhabiting the crevices in the science of
Equal Librium)

Wow, Jeff, you are a really smart guy. It sure is nice to know that you are able to analyze this sand over conduit problem so thoroughly. Heck, I thought the air would blow out thru the sand. I didnt even consider the sand above the air leak to be immovable. I thought the air would find a path to leak out somewhere between the tape and the conduit. I hadnt thought about using neighbor kids. Why would you consider using kids for this project?
I'll assume you wont recommend the OP use water or air to locate the far end of his conduit.

The ARRL information on "extra loss due to VSWR" is may be incomplete in that it may not the assumptions that underly the formula used for the graphs.

The very concept that SWR necessarily increases loss from the matched line loss figure is flawed.

Try the line loss calculator at http://www.vk1od.net/tl/tllc.php to calculate the loss in 1m of RG58 at say 2MHz with loads of 5 and 500 ohms (both VSWR=10).

Now refer to the ARRL... does it explain the difference?

Yeah, but I like playing in the sand. Try this experiment next time
you have an air compressor and nozzle handy. Find a cardboard,
plastic or metal tube at least 3 ft long. A vacuum cleaner extension
pipe will suffice. Plug up the other end with whatever is handy. Blow
air into the center of the tube. Run your fingers around the edges of
the tube and note which way the air is flowing. That's what will
happen if the compressed air is not sufficient to blow 30 lbs of sand
into the air. The air and the sand will flow back into the pipe in
the opposite direction as the compressed air.

Nope. My guesswork is far from exact. Close enough.

>Heck, I
>thought the air would blow out thru the sand. I didnt even consider the
>sand above the air leak to be immovable.

It is immovable, until it moves. That's the real problem. We can
consider the sand to be a solid plug until it starts to break up. As
soon as that happens, it leaks like a sieve. As soon as it starts
leaking, the air pressure available for lifting the sand is
dissipated, resulting in the collapse of the sand pile. Think of it
like a real volcano. As soon as the volcano stops erupting and
belching gasses, the eruption column of airborne rock collapses, heads
for the ground, and creates a messy pyroplastic flow.

>I thought the air would find a
>path to leak out somewhere between the tape and the conduit.

There's plenty of opportunities for air leaks. If the PVC joints
aren't glued, the air pressure will probably separate the lengths of
PVC pipe.

>I hadnt
>thought about using neighbor kids.

Anyone that uses 3/4" PVC for antenna conduit, and then buries and
loses one end, is certainly not a professional underground
construction contractor. He certainly isn't going to use high prices
professional union ditch diggers. The cheapest alternative are the
neighbors kids. I currently have a horde of them working on removing
the blackberries from my hillside. It may take months and result in a
few non-fatal injuries, but it's still cheaper than hiring a landscape
contractor. Also, more fun to watch.

>Why would you consider using kids for
>this project?

They work cheaply. They're familiar with playing in the sand using
shovels and pails. Just tell them it's kinda like at the beach. They
also bounce instead of break at a young age, which makes them suitable
for dangerous tasks.

>I'll assume you wont recommend the OP use water or air to locate the far
>end of his conduit.

I posted some serious recommendations in previous rants. I like
dropping a boson's whistle down the pipe at the end of a small
diameter air hose. Apply air pressure and it should be hear through a
foot of sand. If not, it will surely scare the gophers, which might
be useful.

Hi Jeff,

Well, it's been a coon's age since I've seen vacuum cleaners that
would let me attach to their exhaust - so that's out.

As for driving compressed air into a short (or open). I've done that,
but not for sand excavation. Rather, I've used what was commercially
called the "vortex effect" which separates the two air current flows
you allude to above to create a hot stream and a chilled stream of
air. (Elevated or depressed from the average of the inlet
temperature.) I used this for cooling electronics in a paper mill.
Not particularly efficient, but compressed air was available, and the
VorTec nozzle was a quick and easy solution to their NEMA enclosures.

See:
http://www.vortec.com/support_casestudies.php
or
https://secure.vortec.com/store_products.php?catID=9&prodID=6

This, and some of my fluidic applications constitute a specialized
niche in alternative logic systems. Notably, they all work off
principles of reflected power that demonstrate palpable examples.

Have you ever heard of a shop vacuum?

Usually only available at highly specialized stores such as Walmart.

Hi Jim,

Unfortunately my shopping nature turns me more towards Fry's and I certainly have very little interest in yet another vacuum cleaner (if they offer them). Market forces long (decades) ago convinced me that Hardware skills were in a declining employment segment in proportion to software.

There may not be a software solution to this current problem of locating a buried pipe, but I wouldn't have buried it without some simple binary marker (it's here!). The analog solutions offered are inventive, and I do appreciate them however. One or several are probably far more effective than going to Walmart for a shop-vac (that would only become a permanent altar attesting to my need to use it in justification for its expense).

We always do this at work and lately started doing GPS surveys of new
buried cables marking GPS and survey data on the pictures, This comes
in real handy when you are paying for 4 guys and a rented backhoe to
stand around and wait for you to find a cable,

Jimmie

It is possible for a feedline with a high SWR to have
lower loss than the matched-line loss. For instance,
if we have 1/8WL of feedline with a current miminum
in the middle of the line, the losses at HF will be
lower than matched line loss because I^2*R losses tend
to dominate at HF.

The problem with vacuum cleaners is that they all suck. I have an
ancient Electrolux and a Shop Vac that both have usable exhaust ports.
I also have a Hoover upright and a Hoover cannister in the office that
do not. Y'er right that it's a vanishing breed.

However, you re-read what I scribbled, you might notice that I
suggested that one use the air compressor to pressurize the 3/4" PVC
pipe. That's because the average vacuum cleaner can barely generate
more than a few PSI. They also leak badly. If you're trying to lift
a column of sand or demonstrate backpressure, it's much easier with a
proper air compressor.

>As for driving compressed air into a short (or open). I've done that,
>but not for sand excavation.

I have. The clumsy backhoe operator (me) once dropped a load of dirt
on top of the steel 3" conduit end during construction. I'm also the
idiot that forgot to shove a protective rag into the conduit end. I
spent the next two days trying to figure out how to get the dirt out
of the pipe. I eventually fabricated a cylinder shaped rubber plug
with an eyebolt down the center, dumped some water into the conduit,
and dragged the plug through the pipe with a winch. It took about 5
passes for the water to come out clear. I then pumped out the
remaining water, dragged a sponge through the pipe a few dozen times,
and then let evaporation do the final cleanup. Compressed air was
attempted just for fun, but it was obvious that it wasn't going to
lift the dirt out of the pipe.

Nice. I built several out of the original Amateur Scientist book (which I still have on my bookshelf) in the early 1960's. It worked amazingly well. Much later, I built one out of PVC pipe, which melted. Now I know why they're made out of metal. Never mind the inefficiency. It's the noise they make that drives me nuts. At one point, we had 4 of them in series, with 4 assorted air compressors pumping about 4 SCFM into each, and got it down to about -100C. We started with a group of about 10 lab students, and ended up with a crowd of about 100 nosey students wondering why someone was trying to operate a jet engine on campus.

>This, and some of my fluidic applications constitute a specialized

yeah, when you use the full complex Z0 and probably the full transmission
line equations it gets a bit more complex. but for amateur use that graph
is close enough. the difference between 5 and 500 ohm loads of .07db or so
for 100m just ain't worth quibbling about for normal amateur hf use. unless
you want to argue it out with cecil.

Sorry, I have no argument with Owen. I do have
an argument with people who say replacing the
RG-213 on a G5RV with 300 ohm twinlead all the
way to the tuner will reduce losses on 80m -
tain't so.

Hi Jeff,

I was responding to the broad assortment of methods which included
what was the closest option for me of a vacuum cleaner.

>That's because the average vacuum cleaner can barely generate
>more than a few PSI. They also leak badly. If you're trying to lift
>a column of sand or demonstrate backpressure, it's much easier with a

No doubt and no argument. At one point in my career, I found myself
with a dead weight tester, calibrating a pressure gauge to 10,000 PSI
when the coupling line spit sending a fine spray of pressurized oil
past my face. Took me half an hour to shake off the thought of it
hitting me square.

I've done that too. For a summer of my youth (when dinosaurs ruled
the earth) I would plunge down a manhole with a tethered ball. I'd
plug it into the downhill side, clamber out, and fill the manhole with
water. Then go to the next manhole, clamber down and dig out all the
muck that had been plunged ahead of the tether ball. Repeat for
weeks.

Substituting one central phrase of "Apocalypse Now":
"The aroma of it all! The AROMA of it all!"

>I'll pass. I don't believe in logic any more. Everything can be

Last night I went to a reception for Joseph Stiglitz where he mentioned being a liberal too much (he was apologizing to the group at that point) and I drew him aside to comment that he had no need to explain his bias as this was the first time in our political history when we had two candidates BOTH running against the administration AND the Republican Party. We laughed at that logic.

Everyone needs a shop vac, especially a wet and dry one.

Unless you really like spending a long time mopping floors.

I was once a swab jockey. Mind? when there was no choice you turn
that off.

Hi Jim,

I prefer dry floors. That's why I invested in a French drain. And I
have more floor space than that which would have been lost to a barrel
that sucks.

Ouch. At that pressure, the first few drops of oil will give you an
instant tattoo. An acquaintance recently had that happen to him. He's
now recovering from the skin grafts and laser ablative cleanup.

The closest I came to that was getting a hydraulic fluid shower while
riding as an operator inside a Rose Float (in about 1968). The floats
animation was run by a pony engine and hydraulic pumps. The coupling
directly over me started to leak. After 2 hours in the float
lumbering through Pasadena, I arrived thoroughly soaked.
<http://802.11junk.com/jeffl/pics/jeffl/slides/RoseFloat01.html>
That's me testing the chair position (which was arc welded in place so
it had to be perfect). My feet are resting on top of the electrical
animation switching panel.

These days, the installers doing FTTS (Fiber Through the Sewers) have
all the fun. Instead of summer interns, the dirty work is done by a
robot which installs a SAM (sewer access module):
<http://www.kate-pmo.ch/pages/en/fast.html>
Despite the robotics and improved handling, the packets delivered
still seem to smell of effluvia.

>... as this was the first time in our political history
>when we had two candidates BOTH running against the administration AND
>the Republican Party. We laughed at that logic.

Chuckle. Very true. Worse, the "real" agendas of both parties are almost identical. I noticed that both parties are also against the status quo (which is generally considered awful). That makes me wonder just what they are in favor of actually doing. I would prefer they do absolutely nothing and let the economy fix itself, but that's too much to hope for. Let the lesser evil win in Nov and never mind trying to decode their logic.

I should feel guilty for encouraging this off topic discussion, complete with topic drift, but I don't.

Hi Jeff,

I count it as adding value - even if it is for political education,
sewer management (I didn't mean for that juxtaposition, but Karma
seeks its own balance), and the parade of roses systems control. That
photo was a blast. Did you actually have to cross your feet as part
of the control heuristics?

At the end of Stiglitz's discussion on the cost of the war ($3 to $5
Trillion at a minimum), someone asked plaintively "Don't you have
something positive to offer us?" He responded "We will have a new
president soon."

You either misread my example (it was 1m not 100m) or you labour under the misapprehension that loss per unit length under mismatched conditions is constant at all displacements along the cable.

When approximations that hold under some conditions replace the underlying principles, we dumb down. The formula and graphs for "additional loss due to VSWR" without statement of the assumptions under which it is valid are an example... where now, so many people accept the concept that VSWR necessarily increases loss.

The OP was trying to reconcile calculated losses in a particular scenario, and one of the contributions to error was the "additional loss due to VSWR". It is fine with me that understanding doesn't appeal to you Dave, but you don't need to press that approach on the rest of us.

Owen

(PS: if we take a length of 50 ohm coax sufficiently short that current distribution is approximately uniform, and consider the losses under matched conditions and under a 500 ohm load with same load power where voltage is three times and current is one third, it is intuitive that since most of the loss in practical coax cables is due to I^2R loss (compared to V^2G), that loss will be LESS (than Matched Line Loss)... approximately one tenth in that case... so why swallow the ROT that high VSWR necessarily increases loss.)

> (compared to V^2G)

A quick question. If most of the the cable loss is due to I^2R, how can one explain that the foam versions of common coaxial cables show a much lower loss than versions having solid PE insulation?

For instance RG-213 is rated at 8.5dB loss for 100 meters at 144 MHz, while RG-213 foam at only 4.5 dB. If G is relatively unimportant with regard to loss, how can one explain that a change of insulation material yields such a tremendous change in loss?

Thanks and 73

If you construct a cable of similar outside dimensions but using a foam
dielectric, it needs a larger diameter inner conductor. That accounts for
the lower loss at lower frequencies (typically below the GHz range.)

>
> For instance RG-213 is rated at 8.5dB loss for 100 meters at 144 MHz,

See above.

If you use my calculator (link in earlier posting), it gives you the
coefficients of two terms of the loss model, one is due to I^2R and the
other V^2G. You can evaluate them at any given frequency and determine
the contribution that conductor and dielectric losses make at that
frequency for that cable type.

Does that help?

Those statements about most loss being due to I^2*R
losses are at *HF* frequencies. 144 MHz is NOT HF.
The difference in RG-213 and RG-213 foam is only 0.2
dB at 10 MHz while the difference between RG-58 and
RG-213 is about 0.7 dB at 10 MHz.

why should i swallow your rot that shows when you push the limits of the
equations you get results that 'seem' to defy logic. I understand perfectly
well what you are saying, and i do understand the full complex forms of the
transmission line equations. what i am saying is that for most 'normal'
amateur use the graph presented in the arrl book is adequate. if you insist

on pushing computerized calculations to the absurd limits i'll lump you in
with art and his over optimized ball of wire antenna.

In reasonably well constructed coax cables, the main source of loss up to about 1GHz is the I^2R loss in the centre conductor. The inside of the shield carries an equal (and opposite) current, but the current density is lower so the I^2R loss there is less important. Dielectric loss is usually less important still.

In low-loss cables that have the same outside diameter as the classic PE cables they are replacing, the reduction in loss is almost entirely due to a larger centre conductor. But that change cannot be made on its own. In order to maintain a 50 ohm impedance and keep the same outside diameter too, it is necessary to reduce the dielectric constant of the insulation material.

In other words, they're using foam or semi-airspaced construction because they *have* to. Replacing some of the solid PE with gas may make a small contribution to the lower losses, but nowhere near so much as the advertisers would have you believe. The main contributor is always the reduced I^2R loss in a larger centre conductor.

I seem to remember reading that running coax underground acts like a current choke. However, my memory has many missing bits these days. Is this a true statement about coax underground? In my case the run is about 40' (in a conduit that is about 10" under ground). I am interested only in the normal HF bands.

Lest someone confuses this with an incorrect calculation or estimate:

From TLLC, the matched line loss in dB of LMR400 (a foam coax of similar OD to RG213) is 3.941e-6*f^0.5+1.031e-11*f. The first term is due to R and the second due to G.

At 144MHz, the percentage of power lost per meter due to R is (1-10^-(3.941e-6*f^0.5)/10)*100 is 1.08%. If you do similar for G, the loss is 0.034%, so loss in R is more than 30 times loss in G.

The numbers lead to a better understanding.

Does this make sense? Did I get it correct?

Owen

(BTW for RG213 at 144MHz, the percentage of power lost per meter due to R is more than 6 times loss in G. Most of the loss advantage of LMR400 comes from reduction of the R loss component per metre from 1.6% to 1.1% due to the larger diameter inner conductor.)

A conductor carrying RF currents and immersed in soil behaves like a lossy transmission line. The bahavior depends on the parameters of the soil (amongst other things), so the effect is different in dry sand than in wet clay. Current entering the line will be attenuated along the line.

Your coax is similar to some extent in respect to the common mode current. Placing a single coax in a plastic conduit reduces the loss to some extent compared to surrounding the cable directly with soil.

144 MHz isn't HF, which is where the original statement is valid. At frequencies above around 50 MHz, depending on the dielectric, the dielectric loss starts to be more significant.

Another trap for the unwary, when comparing coax losses, has to do with skin effect and the thickness of the copper or silver cladding on the center conductor. You could have an air insulated coax with silver plated over stainless steel where the loss is actually greater at low frequencies than higher, because the skin depth is greater at low frequencies and the current is flowing mostly in the SS, rather than the copper. (such coax is used in cryogenic applications, lest one think it's overly contrived as an example)

Ian and others,

thanks for your clear explanation, but I still have a doubt that you may kindly clarify.

The 300-ohm TV flat ribbon specifications show an attenuation generally lower than that of plain RG-8, despite the conductors of the ribbon are by far thinner than those of RG-8 (especially than the cable shield).

What am I missing now?

Thanks & 73

Under matched line conditions, the 300 ohm line transfers the power at higher voltage and lower current, one sixth of the current, so even though the conductors might seem relatively thin (RF R is proportional to diameter for wide spaced line), I^2R loss is lower.

300 ohms vs 50 ohms.

Since IR losses dominate at these frequencies, reducing current reduces
loss. The higher Z means more voltage and less current for the same
power. Loss will be 1/36th, assuming all the conductor sizes are the same.

Hi Bill,

The coax shield is no different in loss as is a ground radial wire of
the same dimension. Visit any site that offers the data of Brown,
Lewis, and Epstein to observe that for their experiments at 3MHz, the
amount of radial conductivity drops like a rock well in advance of the
end of the wire (where it would be forced to zero by being open).

You might get it to conduct a bit further by having insulated it from
ground (the conduit), but it is still easily within ground's deadly
embrace.

The analyses I've done using published and realistic values for dielectric (PE and PTFE) and conductor loss indicate that dielectric loss doesn't become significant until the 1 - 10 GHz region, well above VHF.

It's unusual to find a plating thickness that's less than several skin depths thick except at MF and below, or perhaps the low end of HF. It does happen, though. I have some 0.1 inch diameter 75 ohm cable which has a very small center conductor which is made of several strands of even smaller Copperweld wire (thick copper over steel). Even though the copper is probably a sizable fraction of the total wire diameter, the wire is so small in diameter that the copper isn't several skin depths thick at lower HF. It has very noticeably excessive loss at 7 MHz, something I discovered the hard way one Field Day.

Suckers throwing money at marketeers in vast quantities (otherwise
know as the the theory of the "Greater Fool"). Fear is currently
trading at $700 Billion in DC.

If those antennas are made of tinsel with paper thin dielectric, then
you should look elsewhere for vendors. Even a $35 all channel TV
antenna from WalMart would probably take a couple of KW. You could
probably torch the Republican party with 5W from an HT.

Indeed. If you compare a frequency response of a reel of coax with a
plated centre conductor (say, copper on steel) with one with a solid
inner conductor, the former often has a noticeable kink at around 40 or
50MHz. A long time ago, we found this out at work when trying to find
drop cables and miniature cables which we could be used as simulations
of large-diameter, low-loss CATV trunk cables (for use in the design
lab).

At least one major CATV supplier had lots of very large reels of various
lengths the 'real thing' (no pun intended) in a massive trailer parked
immediately on the other side of lab wall. These were patched through
the wall to the test benches. The engineer could then test and adjust
the flatness of the frequency response of wideband amplifiers against
the length of appropriate cable. Thankfully, this technology has largely
been superseded by optical fibre/fiber equipment!

I'd never thought of that. I suppose it applies to any situation where
the feeder is electrically short, and the majority of the current is
less than it would be when matched. I presume that the moral is that
formulas only really work when the feeder is electrically long enough
for you to be concerned about what the losses might be.

Conversely, for a very short line closed on 5 ohm (instead of 500 ohm), the extra loss caused by SWR would be higher than that shown on the ARRL graph (apart from the fact that, when attenuation is so low, the extra attenuation is generally not of much interest, nor it can be read on the ARRL chart).

Evidently the ARRL chart shows some average between the two cases. On the other hand they probably had no better way to synthetically illustrate a concept without giving too many details.

On another thread I was arguing that, if I am correct, the current ratio should be the square root of 6, not 6. Accordingly the loss would be 1/6, instead of 1/36.

>for you to be concerned about what the losses might be.

That's a good way of putting it, but it only applies to the generalized ARRL chart which takes no account of the actual load impedance or the actual feedline length.

Owen's explicit method should get it right in all cases. If you select say 0.125 wavelengths of RG213 in Owen's online calculator, the predicted loss with a 100 ohm load resistance is *less* than the matched loss. If you change the load to 25 ohms, the predicted loss is *greater* than the matched loss.

Both of these results make perfect physical sense because the largest part of the loss is proportional to the square of the current, which will be greater with the lower-resistance load. The two different resistances correctly give different results, yet they both have a VSWR of 2 (based on the 50-ohm system impedance). This shows that VSWR does not contain sufficient information to give an explicit single-valued result.

Owen's program will accept a VSWR input, but it correctly posts a bold red warning that the result is an estimate. If you let the program select the worst-case load impedance for the supplied value of VSWR, you're back on track and it can calculate an explicit result.

Although we're debating fractions of a milliBel here, the debate has shown how often the terms "VSWR" and "load impedance" are used

interchangeably - which they aren't. It isn't a big mistake here, but it can be in other applications. For example, a solid-state PA designed for a 50 ohm load will respond very differently to load *impedances* of 100 or 25 ohms, yet the load *VSWR* is the same in both cases.

I suspect the ARRL additional loss due to SWR charts
are based on 1/2WL increments of feedlines.

Well, if your imagination has failed, simple guessing might suffice.
How many different ways can you make an antenna fail from too much
power? Well, there's arcing across insulators, heating through high
resistance wires, fusing from insufficient wire guage, dissimilar
metals (zinc hardware vs aluminum elements), junction heating or
arcing, and surface conductivity heating (due to poor choice of
element plating).

I'll guess(tm) arcing across the matching xformer as the first to
break things. To match a 5/8 wave antenna, you need a 50 ohm to about
3000 ohm xformer in the base.
Power = Volts^2 / R
500 watts = V^2 / 3000 ohms
V = 1200 volts rms
That will arc nicely through 600v magnet wire insulation. Probably
worse when wet. My guess(tm) is that the secret minor modifications
consists of potting the matching transformer in anti-corona dope or
RTV.

Incidentally, here's a 5/8 wave 6m base antenna that claims to handle
1000 watts:
<http://www.fmbroadcastantenna.com/6meter.html>
<http://www.fmbroadcastantenna.com/images/6M_Coil-Closeup.jpg>
Note the non-soldered coil connections and beefy wire guages.

I think the ARRL graph is based on a well known, but apparently not well
understood formula.

The only text book that I can recall spelling out the assumptions that
underly the integral that produces the formula is Philip Smith's 'The
Electronic Applications of the Smith Chart'.

On terminology, I prefer to not use the term 'extra loss due to VSWR'
because the name implies to many, that it is always positive. IMHO a
better way to speak of the loss is as line loss under mismatched
conditions... and those conditions are more specific than just a VSWR
figure.

In a lot of cases, the approximation is sufficiently accurate... but you
lose visibility of the error when you assume that the approximation is
ALWAYS sufficiently accurate, a Rule of Thumb or ROT for short.

Owen

Yes, I would. Instead of speculating, want me to do an NEC2 model of
the antenna to demonstrate that the characteristic impedance of an
unmatched 5/8 wave ground plane antenna is somewhere between 1000 and
3000 ohms depending on ground radial droop? (Say no.... I'm busy
tonite).

Incidentally, note the photo at:
<http://www.fmbroadcastantenna.com/images/6M_Coil-Closeup.jpg>
5 turns total with a tap at 2 turns. That's a 7:2 turns ratio and a
12.3:1 impedance ratio. 50 ohms in and 613 ohms out. That seems on
the low side, but possibly justifiable to prevent arcing at the top.

>> V = 1200 volts rms

Nope. It might be the aluminum sleeve outside of the matching
transformer that could provide the necessary spark gap. No need for
designing a complexicated transformer in order to have it fail under
power. However, not having a clue what's inside the base, I'll admit
that I'm guessing.

> Electronic Applications of the Smith Chart'.

The formula is developed by integrating I^2 over an electrical half wave of line on one side or the other from the observation point, according to PS. (I don't know the origin of the formula, I am not suggesting that PS invented it, not that he didn't.)

Straight away, that tells you that the VSWR must be almost the same at both ends for it to not matter which end is the observation point, so therefore the first assumption is that VSWR is approximately equal at both ends of the half wave. A requirement for this is that line loss must be relatively low, that the exponential real term in the transmission line equations is close to zero.

If the line section is not exactly a half wave, then the real loss factor might be higher or lower depending on the location of the current and voltage maxima and minima and the relative contribution of R and G to loss. So, the formula may have significant error for short lines that are not exactly a half wave.

For a line that is many half waves, the formula is fine so long as VSWR is approximately constant (now a very low loss line). If the line is longer than many half waves, but not an exact integral number of half waves, then the error in the partial section will be somewhat diminished relatively by the loss in the complete half wave sections.

If a practical line is very long, it cannot qualify as having a constant VSWR (unless it is 1, in which case the formula is unnecessary), so the formula is not suited.

So, in summary, the formula is good for low loss half wave lines, or even longish random length low loss lines, but not good for short random length lines or very long lines.

So, why is the formula so popular?

Could it be that it underpins one of the popular myths of ham radio, that VSWR necessarily increases line loss?

Modern computation tools are better than the 70 year old graphical method. Publication of the formula without qualification with the underlying assumptions treats the reader as a dummy.

Yeah, I know. I just wanted a photo of the typical matching
transformer. I'm not suggesting that the two antennas are in any way
comparable.

Incidentally, there's a slightly better detail of the Diamond DPGH62
antenna at:
<http://www.rfparts.com/diamond/pdfdocs/Parts%20Lists/DPGH62%20list.pdf>
It appears that the lower section has an adjustable length, which
should be useful for tuning to the desired range.

>Interesting, Jeff. I wonder why Diamond would
>specify the mod is good for 52 - 54 MHz, FM only?

I have some guesses as to why chopping a capacitor in the phasing
section might reduce the bandwidth somewhat. However, my guess(tm) is
that there might be some heating at the bandwidth edges which is
aggravated by the higher power levels. Double the input power, all
else being the same, and there's twice as much heating.

The FM only in an interesting oddity. My guess(tm) is that if you use
if for SSB, your peak power might be more than 500 watts, which would
create more high voltage at the insulators, and therefore more arcing.
As always, just a guess(tm).

Also, I'm a bit worried about the 78 mph wind speed rating (which has
magically increased to 80 mph in this chart):
<http://www.rfparts.com/diamond/Product_Catalog/base_station.html>
If you're in hurricane or tornado country, it might be on the low
side. I'm also suspicious about the "heavy-duty aluminum" but with a
shipping weight of only 6 lbs. That seems a bit light for a 21ft long
antenna. It's probably ok, but I like to worry.

I guess I should do an NEC2 model of the antenna, but I'm still
learning modeling and just hate reading more documentation. More gain

means a correspondingly narrower vertical radiation angle. With only
6dBi gain, the vertical radiation angle is going to be fairly wide, so
I wouldn't expect changes in uptilt to be much of a problem.

If you mean native Z (no special secret sauce matching), no, not even
close. If you mean with a simple series L, about 70 Ohms in the ones
that I've built or have kicking around. Add a shunt L to that (not
that it is needed), about 50 Ohms.

What price SWR?

Off by up to an order of 5? To prevent arcing to what? Now that's
what I call marketing - sell in pairs only, phase them, and warn about
possible arcing. Now, that will build lines around the block to buy
them! Antennas for real men throw sparks. (Sparticels for Art's
sake.)

Well, we're both wrong. It seems to be around 350 ohms for the ideal
model. I ran the model of the single 5/8 wave ground plane. See:
<http://802.11junk.com/jeffl/antennas/gnd-plane-02/>
The NEC2 file is tacked onto the bottom of:
<http://802.11junk.com/jeffl/antennas/gnd-plane-02/slides/gnd-plane-02.html>
if you wanna play with it (or find my screwups). Argh, I just found a
small error.

My guess is that the double 5/8 wave with 1/2 wave phasing section
will be about the same impedance. I'll run it tomorrow (when I'm
awake). If ambitious, I'll let the optimizer grind it into something
useful (takes forever on my PIII/933MHz). Stay tuned...

OF course, all this is idealized guesswork. If I had the real
dimensions for the Diamond antenna, the results might make more sense.

>What price SWR?

Zero. Customers pay for gain and leave the VSWR for the techy types
to argue over.

Right on. Teflon coated to help the waves flow off the antenna
easier. Maybe some surf wax to lubricate the waves. Be sure to use
magnetic stainless so that it can be sold as a "wave magnet". A pair
of large balls to form an adjustable spark gap for "over power
protection" for the Telsa lightning effect. Tilt and swivel base to
adjust the takeoff angle. I can go on forever doing this....

That's what I like about antennas. The end users have no clue how
they work, no standards for comparison, no test equipment to make
measurements, and no Consumer Reports articles on which to bias their
opinions. Comparisons are almost impossible as everything from the
test site to the position of the moon have huge effects. Antennas are
magic.

>Failure designed in - special order to get the one designed not to
>fail. Sounds like a bailout candidate.

Nope. Only big failures get a government bailout. Small failures,
like what I just lost on the stock market, don't get bailed out.

The last couple of 5/8ths antennas i made I estimated the series coil ,no tap, at being about 1/8th wl long then prunned a little to tune. This seems to work fairly well but maybe it was just dumb luck.

I have heard that burying your cable will keep RF from coming back in
the shack. From what you say it seems like this is possible but at the
expense of using some of your precious watts to warm the ground.

> formula is not suited.

I have a feeling that the ARRL chart makes reference to the SWR at the antenna, and that it DOES take into account that, for a lossy line, the line portions closer to the transmitter are subjected to a lower SWR.

I try to explain my argument. Let us assume that the line consists of the cascade of many identical line pieces, each having a 1-dB loss, that one can freely add or remove. Adding a piece causes an increase of line loss by 1dB + some extra loss due to SWR. If you add many 1-dB pieces (that corresponds to increasing the total line loss), the chart shows that the extra loss caused by the last added pieces gets smaller and smaller (the chart curves all tend to saturate for an increasing line loss), and this could be explained by the fact that the ARRL formula does take into account the fact that the last added pieces are subjected to a lower SWR (and hence yield a lower extra loss) .

What do you think about that?

I try to explain my argument. Let us assume that the line consists of the cascade of many identical line pieces, each having a 1-dB loss, that one can freely add or remove. Adding a piece causes an increase of line loss by 1dB + some extra loss due to SWR. If you add many 1-dB pieces (that corresponds to increasing the total line loss), the chart shows that the extra loss caused by the last added pieces gets smaller and smaller (the chart curves all tend to saturate for an increasing line loss), and this could be explained by the fact that the ARRL formula does take into account the fact that the last added pieces are subjected to a lower SWR (and hence yield a lower extra loss) .

What do you think about that?

3000 Ohms divided by 613 is one example from above
3000 Ohms divided by 350 is more from the example below

Where 1000 to 3000 Ohms (below) comes from is an utter mystery to me.

>>>Yes, I would. Instead of speculating, want me to do an NEC2 model of

No where in any of your panes do I see anything close to 350 Ohms (R?
X? Z?) and certainly none are close to 1000 to 3000 Ohms

What error? I am not fluent in Card data, but it looks like you've
built a 5/4ths radiator over 4 1/4ths radials.

Either way, a 5/8ths is not a fire breather mismatch and with a small
inductor in the base feed presents a very modest Z and a tolerable
match.

I've done my own sand castings at home. It's not easy and requires
considerable prep and cleanup time. Building a burner, crucible, sand
box, and pre-form are time burners. It took several false starts and
finally some expert advice to get something usable. Don't ask what I
was making.

See:
<http://www.backyardmetalcasting.com>
You can do it in a barbeque with charcoal, but propane is easier.
<http://www.backyardmetalcasting.com/bestfuel.html>
Good luck, but I suspect you can buy the base parts from Comet or
Diamond.

Grumble. I can't seem to figure out what to use for the phasing
contrivance located between the two 5/8 wave sections. The gain
pattern looks awful. Duz anyone have any info/guess/clue/hint on
what's inside the DP-GH62 antenna?

Approximations that depend on VSWR as a load metric can:
1. depend on the integral over a half wave of very low loss line then
apply it as a constant loss loss per unit length; or
2. treat the forward and reflected waves as waves independently subject
to a constant loss per unit length.

I explained the sources of error in extending (1) to the general case in
my earlier post.

Case (2) assumes that the attenuation is the result of (vector) addition
of the power that is lost independently from each travelling wave at any
point, whereas the power lost is due to the effect of currents and
voltage resulting from vector addition of the voltages and currents of
the two waves at each point.

In some scenarios, they may be good approximations, but there are also
scenarios where they are poor approximations. (I gave an example in an
earlier posting where they both fail.)

The reality is that on a practical mismatched line, loss per unit length is not constant with displacement. See my notes on VSWR at varying displacement on a practical line, see http://www.vk1od.net/VSWR/displacement.htm .

Look at Fig 9.

Note that the loss vs displacement line does not have a constant slope, and anything that ignores that is ignoring an aspect of the problem.

Note that in the example, the red line dips below the blue line (meaning loss under mismatched conditions is LESS than matched line loss at some lengths). Any method that prevents that result is ignoring an aspect of the problem.

The loss under mismatch conditions does depend on load impedance, and if you throw away some of the detail and reduce it to load VSWR, then you increase the scope for error.

Is there application for the approximations? Certainly, I use them... but in the knowledge that they are approximations and an awareness of where they are not good approximations and may not produce an adequate answer for the current problem.

Your original posting was about reconciling the chart with some examples, and I noted that the chart itself is a source of significant error in some scenarios.

BTW, your calculations seem to fall into case (2), and if so, are subject to the same errors... though they may reconcile well with a chart based on that approximation.

The effect of the buried cable will be to influence the magnitude and
distibution of the common mode current on the feedline.

Yes, the common mode current flowing on the feedline in the ground will be
mostly converted to heat if the line is sufficiently long. Minimising the
current flowing into the underground section helps system efficiency.

But the measure has been effective in reducing RF levels in the shack.

Hi All,

Add dBd to the mix (or as they write it, dbd):
http://www.rfparts.com/diamond/pdfdocs/DPGH62%20instructions.pdf

"With only 6dBi gain...." where my modeling of a simple 5/8ths eeks
out 2.4dBi, and if we hoped for the best from a doubling due to a
stacked element of equal gain giving us 5.4dBi; then 6 of anything is
gravy on that turkey. Imagine going further with 6dBd! You get
dressing and cranberry sauce too.

And then it arcs over. :-(

Roasted turkey.

It should be enough that it loads up, doesn't warm up, and all the
dimensions are within 1% ballpark or so of everyone else's - or
adjustable to them. Look at the quality of construction, push your
money across the counter to the clerk (can't rightly call them techs),
and take it home.

The same is true of any other kind of resistive common mode choke. But it's an impedance matching situation, so the loss doesn't necessarily have to be significant. Remember that the loss is I^2 * R where I is the common mode current and R is the choke resistance. If R is low, the loss will obviously be low. The choke won't be very effective, however, unless it also has a substantial amount of reactance. If R is very high, the loss will also be low because it will cause I to be low. The only time that loss really becomes a significant fraction of those "precious watts" is when R is in the vicinity of the effective common mode source and load impedance. A properly designed common mode choke will have a high enough impedance (resistive, reactive, or some combination) to reduce common mode current I to a low value -- that's the objective after all.

Please permit me to amplify on what Owen said, because it looks like it might be interpreted. Burying coax in soil has no effect on the signal inside the coax -- the loss of the coax transmission line isn't increased. The lossy transmission line Owen refers to is the line made up of the outside of the coax and, for the other conductor, the Earth. This is the transmission line which carries the common mode current and the one which will be made lossy by burying the coax.

Roy, one of the lingering gaps in my post was that I spoke of a single coax in a plastic conduit. As many readers will recognise, that is an important qualification.

If you put the coax cable inside a metallic conduit, attenuation of common mode current on the coax is much lower because it forms a coaxial TL with the conduit. The next question is what is the CM current on the outside of the conduit, and that requires examination of the end conditions on the conduit.

The other issue, is that people often install multiple coaxs in one non metallic conduit. If they are not bonded together, they may convey energy with relatively lower attenuation by driving the coax outers in differential mode.

I recall a project where understanding the configuration of underground medium voltage and high voltage power entry to a comms facililty was real important in modelling EMP impact. A neutral screened medium voltage cable worked differently to three conductors in trefoil or flat. HV cables were invariably armoured, and the armouring was relevant, depending on how it was treated at both ends. In some situations, 30m of underground power entry cleaned it of EMP, in others, it made almost no difference (though still relevant in modelling).

>about 2 something dB difference IIRC
>http://www.rfparts.com/diamond/dpgh62.html

I can't tell for sure. Worse, the table at:
<http://www.rfparts.com/diamond/Product_Catalog/base_station.html>
also uses dB with one 2.4GHz antenna labeled dBi. The difference
between dBd (dipole) and dBi (isotropic) is 2.15dB. Just dB is a
ratio and is meaningless (or ambiguous) for antenna gains because it
lacks a reference level.

My model of a single 5/8 wave yielded 2dBi gain:
<http://802.11junk.com/jeffl/antennas/gnd-plane-02/slides/vertical.html>
At best, a 2nd element will add 3dB more gain to this resulting in
5dBi gain. My guess(tm) is that the rated gain is really 6dBi (after
a bit of rounding up by Diamond or possibly some screwups in my
model).

Also, I'm still having a difficult time modeling the 2nd 5/8 wave radiator because I have no clue what's inside the phasing section. If you talk to Diamond tech support, I would be interested in this info so I can finish what I started.

Question: How are your going to mount this antenna? I wanna throw in the mounting pole and height above the roof.

I'll work on this more tonite.

Allow me to reassure you that you're doing the right thing. There's
nothing worse than someone that knows exactly one thing well, and
everything else is a lost cause. Such versatility has served me well.
In college, I majored in electrical (not electronic) engineering.
However, to took classes in cooking, tractor driving, tractor
mechanics, music, psychology, and whatever else I could get. There
was little rhyme or reason behind my selection other than to get
enough class units to officially a student and maintain my draft
deferment. All of these accidentally acquired skills have served me
well in the last 40 years. It's also not beneath my dignity to jump
into something new, sometimes RTFM, learn from my mistakes, and
blunder onward to my next learning exercise. When we stop learning
and growing, we die.

The pot belly stove and blower sound like they will work. I did
something similar using refractory brick and a leaf blower. Try to
get a blower that has several speeds as the first one I used blew hot
embers all over the yard and nearly set fire to the deck. Make sure
you have goggles, gloves, tongs, face mask, helmet, chaps, and
whatever else it takes to protect you from mistakes. Learn a bit
about fire safety and how to extinguish various fires. (Hint: don't
use water. The steam will scald you. Use sand instead). If your
father in law is a good teacher, you should do fine.

I goofed. It was near midnight, I was tired, (insert standard
excuses), etc. I even asked for the OP to say "no" to my offer to do
a model.

The coil in the photo has 5 turns and a tap at 2 turns.
<http://www.fmbroadcastantenna.com/images/6M_Coil-Closeup.jpg>
That's a turns ratio of 5:2 or 2.5:1. The impedance ratio is the
square of that or 6.25:1. For a 50 ohm input, that tranforms into a
313 ohm characteristic impedance.

>Where 1000 to 3000 Ohms (below) comes from is an utter mystery to me.

From my faulty memory. It's wrong. Sorry.

>>Well, we're both wrong. It seems to be around 350 ohms for the ideal
>>model. I ran the model of the single 5/8 wave ground plane. See:
>><http://802.11junk.com/jeffl/antennas/gnd-plane-02/>
>
>No where in any of your panes do I see anything close to 350 Ohms (R?
>X? Z?) and certainly none are close to 1000 to 3000 Ohms

See:
<http://802.11junk.com/jeffl/antennas/gnd-plane-02/slides/impedance.html>
The green line is the magnitude of the impedance. I ran the numbers
at 50MHz which yields about 300 ohms. It's somewhat less at higher
frequencies.

See:
<http://802.11junk.com/jeffl/antennas/gnd-plane-02/slides/gnd-plane-02.html>
which shows a vector impedance of 84.6 -j285 at 50Mhz. That tranforms
into:
Z = (84.6^2 + 285^2)^0.5
Z = 297 ohms

>>The NEC2 file is tacked onto the bottom of:
>><http://802.11junk.com/jeffl/antennas/gnd-plane-02/slides/gnd-plane-02.html>
>>if you wanna play with it (or find my screwups). Argh, I just found a
>>small error.
>
>What error?

A typo in the notes on the deck indicating that it's a dipole.
The gain graph is actually the VSWR graph.
The vswr graphs is shown twice.
The drive point on segment #1 is to high above the ground radials.
I'll fix all this later tonite.

>I am not fluent in Card data, but it looks like you've
>built a 5/4ths radiator over 4 1/4ths radials.

Nope. I'll double check later. If run the calcs at 300MHz which has
a wavelength = 1 meter, which causes all the dimensions come out in
wavelength. The GS card then scales it to the exact frequency. I
like to do it this way so that a given design can be rapidly modified
to any other frequency without massive recalculations of the geometry
values.

<http://www.nec2.org/other/nec2prt3.pdf>
"If a frequency card does not appear in the data deck, a
single frequency of 299.8 MHz is assumed. Since the wavelength
at 299.8 MHz is one meter, the geometry is in units of
wavelengths for this case."

Also, I use SY cards to define element lengths, thus allowing the
optimizer to work with these values.

>Either way, a 5/8ths is not a fire breather mismatch and with a small
>inductor in the base feed presents a very modest Z and a tolerable
>match.

Ummm.... 300 ohms is a 6:1 mismatch. Not exactly my idea of modest.

My thanks to the entire group for the excellent responses (mostly :^)
) on my problem. It was only yesterday that I finally had opportunity
to address it.

The RF on the fish line did not work.... just did not seem to couple
and radiate. However, a very very simple procedure (one of you
mentioned this) did work. I had my wife pull and push the fish tape
back and forth while I listened very closely for any sound of it thumping
against the end of the pvc at the far end. It worked. I did not
actually hear it hittingi the duct tape, but I did hear it as it moved
back and forth on the last sweep at the end. It was only about 8 inches
under the surface of the sand (much less than I had thought) and was
located farily easily.

You guys came up with a plethora of solutions which would have been fun
to try.... one of the reasons I posted the question to this group,
even though a bit off topic.

To answer one question, the PVC will only be used for electrical, not
antenna, so the 3/4" is quite sufficient for my needs.

Again, thanks to all. I won't forget some of these methods suggested.

This confusion has been to the great benefit of antenna manufacturers as a tool to mislead customers. A gain figure in dB could mean:

1. Gain relative to isotropic (dBi)
2. Gain relative to a half wave dipole in free space (2.15 dBi)
3. Gain relative to a dipole at the same height over ground (~6-7 dBi typ.)
4. Gain relative to anything else

Furthermore, a gain in dBi could be the free space gain or the gain when mounted at some height over ground, a difference typically around 4-5 dB.

Unless the reference and conditions are clearly stated, the gain figure means really nothing at all. And, even when the reference and conditions are clearly stated, can you trust the source of the claim?

My guess(tm) is that the phasing section is an inductor. If you have
an LRC meter, a measurement might be helpful. If you want a decent
model, get out your tape measure and post some accurate measurements.
Incidentally, when measuring the ground radial lengths, measure from
the vertical center axis. If you take a photo, plant a yard stick or
ruler somewhere in the photo.

>screwed a couple feet into the ground. Total HAAT of the antenna's base
>should come out to about 12 feet,

Ok, I'll use 12 ft above a "typical" ground. See:
<http://11junk.com/jeffl/antennas/gnd-plane-05/>
This is my latest attempt at 2nd guessing what's in your slightly used
DP-GH62 Diamond antenna. Instead of a proper phasing section, I just
used a quarter wave stub. Seems to work (although far from optimum).

So far, the results are:
Freq = 50-54 MHz
Gain = 7dBi
Takeoff angle = 12 degrees
Impedance = 120 ohms @ 50 Mhz, 300 ohms @ 54MHz. This needs work.

The ugly vertical radiation pattern can be surely improved by feeding
this mess into the optimizer in 4NEC2. I'll do this, along with all
the other things I promised to do, when I have more time.

I still don't have an answer as to whether the spec sheet 6dB gain is
dBi or dBd. No way to tell from the model.

"Off by an order of 5?"

A perfect match may be easily obtained by adjustment.

Such antennas, colinear or Franklin Arrays, have long been used by broadcasters to increase their signal intensities. As antenna height increases, the radiation is first concentrated increasingly along the horizontal until the antenna reaches a length between one half and five eights wavelength, after which high-angle lobes appear.

A clever way to adjust the antenna`s drivepoint impedance to match its feedline is shown on page 15-25 of the 20th edition of the ARRL Antenna Book. The lower half of the colinear is connected to a quarter-wavelength short-circuited stub to create a J-Pole Array of sorts. The array is called "The Super-J Maritime Antenna", It is notable for its gain and lack of radials to poke eyes when the boat pitches and rolls.

5/8-wavelength gives about 1 dB gain over 1/2 wavelength and a stack of two gives a maximum of about 3 dB gain over a single 5/8-wave radiator.

The book says:
"The Super-J offers a gain of about 6 dB over a quarter-wave whip and about 3 dB over a 5/8-wave antenna

So.... I fed it to the optimizer (chomp, chomp, etc), this time
remembering to set it to only optimize at one frequency, not the
entire swept range (which would have taken 9 times as long to grind).
I set the center frequency to 52Mhz (so I can the results on the
frequency sweep). The only thing I changed was the length of the two
5/8 wave elements. The pattern looks much much much better. Good
enough.
<http://11junk.com/jeffl/antennas/gnd-plane-05/>

Freq = 50-54 MHz
Gain = 7dBi
Takeoff angle = 10 degrees
Impedance = 130 to 180 ohm.

Problem is that loss is proportional to signal frequency through the earth, A low audio tone is much more appropriate. With a low audio tone on an insulated conductor buried in the earth with reference to a ground rod or ground bed, the conductor can be traced for miles. I`ve traced 4-ft. diameter poorly insulated steel pipelines for 8 miles or more and they were buried several feet down for protection.

Reception can use a relay coil to sense the audio signal which is fed to an audio amplifier and earphones. The coil core points toward the conductor.

From the angles made by the core on both sides of the conductor the depth of its cover can be closely estimated.

During WWI, Heinrich Barkhausen was working with army field telephones that exhibited strange whistling sounds, unrelated to the war communications. These sounds were the RF emissions of lightning in the AF band. What is more interesting is that the mode of propagation was along Earth's magnetic flux lines, and the scale of propagation was hemispheric.

As a byproduct of this research, Barkhausen suggested subterranean communication employing a widely separated pair of rods in the earth, and driving them with audio frequency communications. Range was reportedly a function of the distance between the rods. The receiver used the same earth connection method.

This was the subject of a Popular Electronics article in the mid 60s.

Not reported in that journal, Beverage of antenna fame was working at the same time trying to develop a reliable RF communication system for sending orders to troops in the field in Europe, from the US. His system was a ground level wire of several 10s of miles long, oriented end-on towards Europe. Troops could hear the US broadcasts in the field with unsophisticated equipment. However, transmissions back to the US didn't fare as well. They were overwhelmed on receive by the back side orientation of the long wire towards the Caribbean and its summer electrical storms. Dr. Beverage solved that by extending the wire in that direction too and with termination.

Those frequencies were easily 30 times, or more, higher than Barkhausen's suggestion - hence the very looooooong wire.

While looking for a way to get a little more bandwidth out of an 80 meter antenna, I mocked up an antenna in EZNEC that was thick. I plan on making an antenna with spreaders and run 4 wires on each leg of the dipole.

I emulated this in EZNEC by simply making the wire thickness quite thick, ranging from 4 inches to a foot.

The interesting thing was that as the thickness increased, the antenna length decreased for min VSWR.

Is this a real thing?

Franklin antennas at MW broadcast frequencies are quite tall, and aren't really that common. A notable exception is KFBK, which at 1530 kHz, has a short enough wavelength to make it practical. McClatchy was a very engineering savvy company.

I am the original poster of the question about the current-choke effect of underground coax. I mentioned HF bands, with multiple coax runs (and control cable runs) inside a 3" PVC conduit about 10" (top of PVC) underground. The conduit is about 50' long. This is probably a very common situation.

Do I understand the sum of the comments correctly?
- A single buried coax (not inside a conduit) will experience a significant current choke effect.
- Multiple coaxes (and other cables) inside a non-metalic conduit will experience widely varying effects, depending on lots of parameters that would be difficult to quantify in common usage.

One of my coax runs is for a half-sloper that is not very well matched at any frequency. I detect no RF feedback into the shack (checking with the little MFJ RF current meter, among other things). I had been wondering if I should place current choke(s) on the coax on the tower, but I gather there is probably no need for them.

The instructions for my half-sloper (Alpha Delta DX-B) say that an RF
Choke (6-8 turns of the cable in an 8" coil) should be used at the
feedpoint (6-8 feet from the top-hat).

Yep. It's called a "cage dipole". See:
<http://www.smeter.net/antennas/wire-cage-dipole.php>
with a program to help with the numbers:
<http://www.smeter.net/software/dipcage2.exe>

Even the ARRL uses them:

Richard Clark wrote:
"These sounds were the RF emissions of lightning in the AF band."

Richard also noted whistling sounds in army field telephones. I`ve seen these audio radiations called "whistlers".

My efforts were to locate buried pipelines by a more convenient method than bouncing a metal pick off of them. Pipeline rights of way can be wide and pipes are often not where one may think but may be at odd distances from the center of the right of way.

Connecting a signal to the pipe is much more effective than bouncing signals off the pipe or detuning a metal locator with the pipe. Another pipe tracing method in use is a vehicle (pig) launched into the pipe. The pig contains a pneumatic hammer which produces so much noise that it is easily heard through all the ground covering the pipe. Effective, but it is not cheap to launch and recover pigs.

I`ve found broken pipes at the bottom of the Brazos River in Texas and around offshore platforms in the Gulf of Mexico.

My efforts began with the availability of cheap SCR`s. I placed them to key the output of cathodic protection rectifiers at a low audio frequency rate. It worked well.

For more portability, I constructed a complimentary symmetry bipolar power transistor generator which incorporated a 400-cycle Variac. The generator was adjusted to produce a 12-Hz switching rate which proved to work well. Output of the Variac was adjusted to give maximum power tnto the pipeline wherever it was used from the switched 12 V automobile battery. Connections to the pipeline are readily available at the cathodic protection test points at intervals of several miles all along the pipe.

Best regards, Richard Harrison, KB5WZI

It would define a plane beyond which current is substantially reduced
which would raise the current available for contributing to radiation.

Jeff Liebermann wrote:
"---calibrating a pressure gauge to 10,000 PSI when the coupling line split sending a fine spray of pressurized oil past my face."

I had a similar experience but at about 1/10 the pressure. It was exciting nonetheless.

I was on watch in the engine room of an LSM in the middle of the Pacific during WW-2 and we were cruising at our usual 10 or 12 knots but alone, that is not in a convoy.

We were equipped with (2) 1800 HP 10-cyl opposed piston Fairbanks Morse engines. To reverse an engine it is stopped then restarted with reversed rotation. This is accomplished by shifting the position of the camshaft within the engine with the engine controller. There is an automatically operated electric engine brake which clamps the engine shaft to stop its rotation during its rotation change. It has an enormous solenoid which holds the brake off while the engine is running but this can be defeated with a mechanical stop and a switch to save solenoid power if direction changes are unlikely. That`s how we were running to conserve power unescorted at sea.

Suddenly the annunciator in front of me jinggled and ordered "Full Speed Astern". Without switching shaft brake power back on I complied. Suddenly the engine room was full of diesel oil mist, water mist, and smoke. I couldn`t imagine what had happened, but the engine started fine, thank you. in the reverse direction but I couldn`t see my hand in front of my face. After awhile, it dawned on me what had happened. Compresson pressure had fedback into the air compressor system blowing its pressure relief valve and filling the engine room with water from the compressor tank and diesel fuel from the engine cylinders. It was a mess but the exhaust air curculation soon cleared the atmosphere and no harm was done. Never again did I forget to enable the shaft brake before reversing engine directions. I was promoted to MoMM 3rd class and put in charge of my watch. My battle station was gun loader on the 40mm anti-aircraft guns.

Best regards, Richard Harrison, KB5WZI

Thats a suggestion that I would have liked to have tried. I have the
generator, and could have easily fabricated a "receiver". Oh well.
Another technique to add to the repertoire !

The effect is clearly shown in Hallen's curves which appear in many of the
standard text books (e.g. Jordan & Balmain, Electromagnetic waves and
radiating systems). There's certainly a likelihood of greater shunt
capacitance at the feed point, but if the limbs are made conical - radiating
geometrically from the feedpoint - then this doesn't apply. In that case,
Schelkunoff might be of some help.

Bill,

Go back and read your post. I don't think there is anything that states
or hints multiple cables, nor did you state the size and type of conduit.

The larger the conduit, the lower the common mode attenuation for a given
conductor size as more of the dielectric subject to the highest field
strengths is low loss air.

Broadly, don't expect that multiple cables work as a single coax. I gave
some reasons in my earlier post.

The common mode current is a standing wave. (Confusing concept for some!)
That means that measuring its amplitude at one point using the "little
MFJ RF current meter" gives only a limited perspective.

Nevertheless, you have other indications that there is not a problem.
Perhaps you should leave it alone if it is working adequately.

A further benefit of a buried feedline not already mentioned is that it
does protect the conductors somewhat from radiated energy

Arnold B. Bailey in "TV and Other Receiving Antennas" agrees with Jim. Bailey writes on page 317:
"We should expect such thin rods to be resonant when their physical length is slightly less than a free-space half-wave length. When the rod is thick, the effective velocity along the rod is considerably less than the free-space velocity, thus reducing the wavelength proportionally."

The above may be grist for Arthur`s mill.

Bailey produces emperical equations (equilibrium?), graphs, and worked examples for various cross sections.

Some might argue, though, that the reason the effective velocity is less is because the sqrt(1/LC) term is smaller because C is bigger because of the increased surface area. And that might not be far from the truth for a restricted subset of antennas.

All of this kind of confusion is trying to make one sort of model (a transmission line) fit something else (a radiator). Just like the things that treat the antenna as a lumped RLC.

Hi Jim,

I've seen this kind of assertion made before, generally as a blanket
prohibition/warning/incantation/supplication/condemnation - but never
with any demonstrable problem that wasn't an example of designed-in
failure suited to the argument.

Lest there be any confusion: an antenna IS a transmission line.

The clarity to this confusion starts with the Biconical Dipole. S. A.
Schelkunoff describes it as a "Linear" antenna and used transmission
line math to build the mathematical model for the thin wire dipole in
his classic publication "Theory of antennas of arbitrary size and
shape," Proc. I.R.E., 29, 493, 1941 and S. A. Schelkunoff, "Advanced
Antenna Theory, " John Wiley and Sons, Inc., New York, (1952) I'm
inclined to allow the weight of his work stand until someone tips it -
or can demonstrate I incorrectly read his thesis. Somehow given the
weight of authorities (Ronold King being one) that cite him for this
very reading (specific to the correlation) are abundant, I will await
heavier lifting to tip the math.

Accessible reference work can be found by searching the PTO with his
patent number: 2235506.

In fact, there is a formula for calculating the Z0 of
a single horizontal transmission line wire above ground.
#14 wire at 30 feet is very close to 600 ohms. #14 wire
at 30 feet describes a lot of dipoles.

Are there any calculations or charts for centre impedance of a dipole in
free space, starting from zero length, and going out to infinity?

I think that what you're looking for is in Kraus "Antennas for All
Applications", page 446 - "Self-impedance of a thin linear antenna".
The formula given is based on the induced-EMF method... it's an
approximation which apparently works well for cylindrical antennas
whose length is at least 100x the diameter.

Thanks for that. I've found a free download of a PDF copy (18MB) at:
http://www.badongo.com/file/9893801
I'll have a look to see if it is what I want.

I would have thought that the feed impedance of a dipole at a wide range
of frequencies/lengths (ie 'very short' to 'very long') would have been
fairly typical rule-of-thumb required information for those interested
in antennas. However, it does not seem to be!

Oh... if rule-of-thumb is good enough for your needs, then it's not too difficult to summarize. There's a nice chart on page 2-3 of the ARRL Antenna Book.

You should consider the resistive, and reactive portions of the feedpoint impedance separately.

The resistive part rises from zero, up through a nominal 50 ohms or so at resonance (just under 1/2 wavelength), up to several thousand ohms at second (or anti-) resonance. If you plot the impedance-vs.-resistance relationship with the doublet length on a linear scale and the resistance on a logarithmic scale, it's not too far from being a straight line through much of this range.

Between second and third resonance, the resistance drops back down to around 100 ohms... between third and fourth, up to several thousand ohms again, and so forth. As the doublet continues to get longer, the feedpoint resistance oscillates between low (odd-resonant) and high (even- or anti-resonant) values, with the oscillation becoming less and less as the doublet gets longer (think of a damped sine wave). In theory it'll eventually settle down to 377 ohms.

The reactive portion of the impedance also oscillates as the doublet gets longer and longer. Between an even-numbered and odd-numbered resonance it's capacitive, dropping from thousands of ohms of negative reactance, to zero at the odd resonance. It then becomes inductive, rising to several thousand ohms just before the next even (anti-) resonant length is reached. As the even-numbered resonance length is passed it falls abruptly from very positive (inductive) to very negative (capacitive), and then begins to return slowly to zero at the next odd resonance.

These excursions from positive (inductive) to negative (capacitive) continue, and also fall in their absolute value as the doublet gets longer and longer. Once the doublet is "sufficiently long" its reactance pretty much vanishes and it looks like a 377-ohm resistance.

Near the resonant lengths, the value of the reactance is changing rather more rapidly than the value of the resistance.

The same basic principles apply fairly well to doublets that aren't in free space, but ground reflections, mutual coupling with other antenna elements, etc. have a big effect on the actual values. Few of us have the luxury of stringing up an 80-meter longwire doublet in free space, alas :-)

It gets repetitive after a while.

Arnold B. Bailey has "Graph of the resistance of a center-fed antenna near first resonance and below" on page 343 in "TV and Other Receiving Antennas". Then on page 348 Bailey has: "Various orders of resonance of thin center-fed antennas, showing the current loops and approximate radiation and antenna resistance in each case.".

You're right, but in many situations, it's not a uniform transmission
line, by any means. The Schelkunoff analysis is quite elegant.

And, interestingly, a LOT of amateur antennas don't meet this slenderness constraint. Wire dipoles hanging in the air do. Fans, cages, etc., often don't.

No problem with the model, just awareness of the footnotes and limitations (which often get omitted in the less rigorously reviewed internet literature..)

Yes, rule-of-thumb is more than good enough for me! I has a sneaky feeling that the feed impedance would end up at 377 ohms (impedance of free space).

Many years ago, from some tables compiled by one of the many Wu's involved with antenna theory and design, I plotted Zin vs antenna length on a Smith chart. As the spiral progressively wound its way inwards with increasing antenna length, it seemed that it was heading for something between 200 and 600 ohms, so I thought to myself, "377 ohms?" Unfortunately, the table stopped when the antenna was about 5 wavelengths. I haven't seen similar tables since.

On the other hand, the propagation velocity of coaxial cable of constant outer conductor ID is independent of the inner conductor diameter, even though the capacitance per unit length increases as the inner conductor diameter is increased. Clearly one must be careful about attributing the effect to a single cause like increased capacitance.

I haven't noticed in this thread any reference to Ronold W. P. King's work. His writings should give more insight into the subject, if you can get deeply enough into them. It's discussed empirically in "Transmission Lines, Antennas and Waveguides," (with lots and lots of interesting graphs showing the effect from various viewpoints) but you can probably go deeper into the theory than you need in his other books and papers on linear antennas.

Cheers,
Tom

I'm slightly bow legged so crossing my feet is a more natural resting position. The resting position was very important at the start of the Rose Parade. The floats, horses, cars, etc all start getting organized at about 4AM. The parade starts at 8AM. The floats are never totally completed by New Year's day, so frantic last minute work at the starting point was normal. At this point, none of those involved have had more than one or two hours sleep, so a functional sleeping position is a basic requirement. I installed padding on top of the control panel for my feet.

I think I only managed to get about 30 minutes of sleep before the unexpected happened. In 1968, we were behind an equestrian unit. After standing in essentially the same spot for about 3 hours, the horses deposited quite a pile of droppings on the pavement. There was a false start somewhat before 8AM. All the floats and horses lurched forward a few feet, placing our float directly over the pile. Besides the smell, the real worry was what would happen if the leaky hydraulic coupling mixed hot hydraulic fluid with horse dung. I was ready with a large fire extinguisher. Fortunately, nothing happened but we all nearly vomited from the stench.

If you look a the photo:
<http://802.11junk.com/jeffl/pics/jeffl/slides/RoseFloat01.html>
you'll notice a large hinge point directly above my sleeping form. Part of the animation was a young boy, sleeping in bed, who raises up and scratches his eyes, when he sees the toys at the foot of the bed come alive. The kid was huge, thus the giant hinge. It worked fairly well throughout the parade. However, when drove the float back to Pomona for disassembly, it was discovered that all the 5/8"(???) bolts holding the boy to the hinge frame had halfway sheared through.

This is the current animation system:
<http://cpprosefloat.org/site/page.php?23>
In 1968, it was several partly insane students, flipping switches and toggling valves by hand. Cal Poly tended to win the animation prizes.

To bring things back to ham radio antennas, we had a Motorola Breakie-Backie "portable" radio in the float on 2 meters. Tubes, vibrators, wet cells, and muscle. It sorta worked, but the chicken

wire covering the float made a very effective shield. The antenna ended up hanging under the float as we didn't want it visible on top. Someone saw the "loose wire" and clipped it off just before the start of the parade. I made a replacement out of some baling wire. It worked, but about half way through the parade, the vibrator power supply quit. Oh well.

Which was the original intent of my comment. Fat radiators are shorter
at resonance than thin ones, and the details of why are not simply
explained by something like "capacitance effects", although such an
explanation may sort of work over a limited range.

It's a challenge to put antennas on floats and meet the TORC
requirements for only vegetable matter to be exposed. We got a special
dispensation for our 23cm ATV from the JPL float.

Things sure have changed in 40 years.

Nicely done float. How tall is it? We had stability problems with
some of the floats. The parade route was fine, but entering Victory
Park at the end was tricky. One year, some of the floats almost
tipped over.

Also, my fault tolerant memory has failed me once again. The snoozing
photo of me is from of the 1970 float:
<http://cpprosefloat.org/site/plugins/autogallery/autogallery.php?show=7.Past%20Floats%2F350.1970.jpg>
The float consisted of 3 islands, connected with big long throw
hydraulic rams. The float could be contracted to about 35 ft or
extended to 59.99999 ft. The fun part was turning the Orange Grove to
Colorado corner in front of the cameras, while simultaneously
extending the float. Some officials didn't know which way the float
was going to go and ran for cover.

The sheared hinge bolts were from the 1971 float:
<http://cpprosefloat.org/site/plugins/autogallery/autogallery.php?show=7.Past%20Floats%2F340.1971.jpg>
It also features an elephant toy, with targeting controls for a small
water pump and nozzle in the trunk. That was banned the following
year.

I guess I wasn't too clear. I wanted to use one switch each for two ladder line lead ins. Since no one I can find makes arrestors for ladder line I am building my own from spark plugs threaded into a big copper plate which is grounded with copper strap to 5 ground rods in a fairly small circle outside the shack window. It's about 70 ft to the 200 amp service box from the bedroom I am using for my shack.
I just won a bid on ech bay for a double throw make before break knife switch which I'll be using also. I'm going to buy one of those MFJ window lead through plates with multiple ladder line connectors or maybe make my own version.
I am wondering, instead of using just two spark plugs, if it might be more effective to use 3 pairs in line with the first pair having really wide gaps, the second having a medium gap, and the third having a small gap around .035"? I am going to enclose them to keep them dry and they will be grounded to the same rods as everything else.
I'll also have a Drake R-8 receiver in my bedroom hooked to an Evesdropper trap dipole with a Zap Trap arrestor on the co-ax. It's too far to run a ground to the other end of the house so I plan to ground it outside of my window. I know that's not the best way but I don't want to run an 80 foot ground cable to the shack ground.
Thanks for all the good advice. 73 Gary N9ZSV

Gary,
The 'spark gap' type arrestor is about the most worthless you could possibly use. More than one reason for that, the simplest being that by the time it ever bridges that 'gap', it's already gotten to the radio (path of least resistance). Diverting 'some' of that lightning strike is probably better than none though, maybe. Good luck.

Doc, what else can you use for ladder line? Everything I've found is
for co-ax only. Parallel two co-ax arrestors?
I definetly want to run open line as I am going to have a long run to
the antennas. I live on a 29 acre heavily wooded 100 foot hill top in
western Arkansas so I have lots of room for -big- antennas but can
only afford homemade wire designs.
Thanks and 73 Gary N9ZSV

I see why you want to ground close to the shack for your single point ground. This is good. But you will then have two grounds. One being the ground outside your window and the other being the service entrance ground with all the "green wire" grounds connected to it (the 3rd conductor in all your ac line cords). When there is a strike there WILL be a potential difference between these two grounds. That means for those few microseconds they will NOT act as one ground and therefore there will be currents flowing between these two points. You don't want this happening. The NEC code requires you to bond your external grounds together, meaning you should run a conductor outside your house from the shack ground to the service entrance ground. It is a good idea to install ground rods every 16 feet along this run. And the same conductor should be connected to any tower ground you have as well.
There's tons of information on this subect. The antenna email reflector archives is a good one, as well as the QST series about 4-5 years ago.
I know you don't want to do it, but the purpose of that 80 feet of wire is important. Without it, all of your other work could be for naught.

There is an alternative. Run a #2/0 (67.4 mm^2) bare copper buried 1 foot (300 mm) below grade between them. Bit of a pain, but bonds the two grounds right proper.

It is also dependant on what kind of equipment is connected as well.
If it is just a Rx, a Telco type would be appropriate. If a high
power Tx perhaps an electric service entrance type would be more
appropriate.

70 & 71? Maybe you met Dave Steinfeld of TORRA . I worked with him
for some years back in the day (80's).

Nope. I don't recall the name. I only associated with radicals,
leftists, protesters, anarchists, dissidents, draft dodgers, and a few
engineers. If he was anything resembling a normal student, I probably
didn't meet him. Also, I don't think that TORRA existed in 1971 and
before:
<http://www.torra.us/id4.html>
There were very few active hams involved in construction of the floats
at Cal Poly Pomona. I think there were only 2 or 3 electrical
engineering students involved. At the time, the design and
construction was dominated by Agricultural Business Mgmt students. It
was easy to tell the difference. Engineers wore cowboy boots and ABM
students wore suits, string ties, and carried brief a case.

I'd just use 2 coaxial gas tube suppressors, keeping the parallel spacing the same as your ladder line. The coaxial suppressors just have the center conductors going straight through, the little gas pellet barely making contact inside.

Sorry, been away for a while, but I'm back.

Certainly the capacitance may play some small part. But does added
capacitance increase bandwidth to the extent - or at all - that is
achieved by the cage or very thick dipole?

Richard Harrison's reference to Baily regarding velocity is interesting.
Why would the velocity be less at increased width? And would that
increase the Bandwidth?

Nope.. that's why "increased capacitance" is a bad model.

It's not clear why you'd need ground rods along your NEC bonding jumper.
If you're trying to make it do double duty as part of a grounding
ring, maybe? But then, it's the "grounding electrode", and can't serve
as the jumper.

Depending on the distance, too, the bonding wire's not going to help
with the microseconds of transient (as the transient propagates down
that bonding wire)...

Electrical safety ground (green wire) is one thing, Lightning
dissipation is another, and common reference potential is yet another.
The first two have to be connected because of NEC. The first and third
are usually connected because of coax connectors with the shield
connected to the chassis.

But in terms of minimizing transient damage to your equipment, whether
or not it happens to be grounded isn't as important as whether all the
equipment goes up and down together. You could put it all in a metal
cage and suspend it from an insulator and let lightning hit it, without
problems. (people do this for HV measurements on tesla coils and EMP
testing)

And the same conductor should be connected to any tower ground you

Better to run fat Copperweld AROUND the house and clamp to several ground rods then rather than having lightning going THROUGH the house from one ground point to the other. Everything you do should make Primary, secondary strikes and surges want to drain outside and away from the house/shack/site.

A large coil or high value resistor is a good thing for bleeding off static charges on a line so that when you throw the switch, nothing goes through you to ground. It is common for antennas that don't have some DC grounding feature to build static charges if open. Your antenna tuner or the input transformer of your receiver has to drain that. Polyphaser makes good coaxial type surge protectors, but I'm not sure about Ladder line. The gap type arrestor does have limitations because you have to keep the gap wide enough to avoid problems with the transmitter. Multiple series gaps only raises the firing voltage, but the breakdown voltage will be set by the largest gap in the series. A gap at .035 will fire at about 2-10kv depending on humidity. You only want it wide enough so that it won't arc when keying the transmitter. If there is a direct hit they will probably explode or at least blow the electrodes away.

I would seriously read up on the situation in addition to asking questions on a newsgroup. Polyphaser may still have a free publication you can order that explains things in depth.

Humidity doesn't change the breakdown voltage very much. In fact, increasing humidity increases the breakdown voltage. One correction table for a "rod gap" with 1/2" square electrodes has a 10% correction going from 15 torr to 30 torr water vapor pressure and a -16% correction going from 15 to 2.5 torr, which is nowhere near the 5:1 variation cited above. Interestingly, on this basis water vapor is a better insulator than nitrogen, since density of the humid air is actually less. Typical breakdown voltage tolerance on a rod gap is +/- 8%.

3795. Automatic tuner range

Newsgroup: rec.radio.amateur.antenna

Source record: 20769

The various automatic antenna tuner/matcher manufacturers list a tuning range in Ohms - e.g., 6 - 1000 Ohms. The question I have is to whether that value is the magnitude of the impedance (which correlates to SWR) or the real part of the impedance (since the tuner should be able to cancel out the reactive part of the impedance). W0BF

>construction, etc.

My Real Media player is having its usual bad day. I'll look at it
later.

I forgot about the overpass. That would be a problem. One year,
someone built a float over a large fork lift. The plan was to lower
it at the overpass and again at the park entrance (due to overhanging
wires). When the forks were lowered, the skin of the float was
shredded. Someone used baling wire to tie together the ends of the
chicken wire skin at the junction. Oops.

Cal Poly traded space in the Rose Palace with D.E. Bent and Sons. I
think he retired in about 1978. We supplied him with surplus labor
(mostly for decorating and handling flowers) in trade for floor space
and "borrowing" tools. It was a very professional operation.

One of the funniest things was watching Disney Animation attempt to
build their first animated float. Everyone expected big things from
them due to their experience at Disneyland. As expected, the float
had more moving parts than stationary. Just one problem; Disney ran
on pneumatics instead of hydraulics.

The centerpiece of their design was a rather large globe with a
satellite spinning around it. The globe was bisected at the equator
with a cantilever rod supporting the satellite. It, and other moving
parts, sorta worked. Then, they added the flowers and watered them.
That added lots of weight, which they hadn't expected. The support
rod bent and had to be reinforced. Instead of smoothly orbiting the
planet, the satellite lurched and jerked its way around the globe. The
pneumatics could not overcome the added friction. The pressure just
built up and up until the satellite suddenly lurched free. This was
repeated every minute or so. I vaguely recall that it finally died
about half way through the parade when some hose or fitting finally
broke from the concussions. By then, all the flowers had been
catapulted off anyway.

neither, really. What it probably means is that, theoretically it can transform a resistive load of 6-1000 ohms to 50 ohms.

You actually have to look at the available L and C and decide if it can tune a particular reactive load at a particular frequency. The step size for L and C will also determine how good the final match is.

You can write a little program (or spend some serious time with a smith chart) to iterate through the various possibilities, essentially working backwards from a 50 ohm load impedance to see the possible input Zs it can match.

I have some pipe that I had run for an outdoor spigot that I never
finished installing. To test a method of finding it I shot some air
into it the other end was pretty easy to find by listening. I could
hear the rush of air and a lot of gurgling. My dog actually found it
in the roses bushes before I did.

That was off the top of my head so I stand corrected but there ARE variations based on other real world stuff like air pressure and dirt on the insulators. 5-20kv for inside an engine is real world but that depends on other stuff too, like what kind of spark-plug, compression, resistors, mixture, timing, but I digress. The point is the gap may have to be adjusted for best results and might be too wide for protection. I invited him to read up on the subject because I have other projects I have my head into

So what are your experiences with spark gap transmission line arresters? Perhaps you have the precise gap he should be using? My dim recollection is of a chart for the transmitter power in use.

Mike, N3LI wrote:
"Why would the velocity be less at increased (antenna element) width?"

Let B = the phase velocity on the antenna element, in radians per unit length. 2pi/B = wavelength on the element.
Therefore, 2pi/B=velocity of phase propagation.
Due to the behavior of of open-circuited transmission lines and open-circuited antennas:
B=2pif times sq.rt. of LC radians / unit length.

2 pi f / B = velocity of propagation.

It is intuitive that a fat antenna element has more L & C than a thin element and thus a lower velocity of propagation.

Best regards, Richard Harrisob, KB5WZI

I have some pipe that I had run for an outdoor spigot that I never
finished installing. To test a method of finding it I shot some air
into it the other end was pretty easy to find by listening. I could
hear the rush of air and a lot of gurgling. My dog actually found it
in the roses bushes before I did.

Jimmie

Hi Jimmie

That "air" idea wont work, Jeff told me so

Quote Jeff --

"Welcome to rec.radio.amateur.antenna.physics

Ok, let's do the math. Dry sand weighs 100 lb/cubic-foot. There's
about 1 ft of sand above the end of the 3/4" conduit. The weight
action is roughly conical, so the volume of sand involved is (my
guess) about:

100 lbs/ft^3 * 1/3 = 33 lbs of sand.
All that it acting on a 3/4" diameter pipe, with a cross sectional
area of about:
Pi * 0.75" = 2.4 in^2
Therefore, the pressure exerted by the sand is:
33 lbs / 2.4 in^2 = 14 PSI
So, if he can pressurize the pipe to more than 14 PSI, he can lift the
column of sand sufficiently to keep it from dribbling into the pipe.

Of course, it's not that simple. Laminar air flow, pressure gradients
across the conduit, and the effects of the duct tape will ruin my
simplistic guesswork. Worse, the back pressure created by the
immovable column of sand will force some sand particles into the
conduit around the edges with the "reflected" air pressure. In the
middle of the conduit, the air flow is all out of the conduit, but
near the edges, it could easily be the other direction. I'm also
assuming that the sand is a perfect air seal, which it's not. To
prevent all this from happening, the minimum air pressure should be
about twice the 14 PSI, which is easily achievable with an air
compressor, but not a vacuum cleaner.

I'm also trying to imagine how the process will work. I see an air
compressor pumping madly away as the neighbors kids furiously dig
around the resultant sand volcano, as sand rapidly refills the conical
hole. In my never humble opinion, there's no way to prevent sand from
dropping into the conduit if the duct tape seal is broken before
excavating the end of the conduit.

Once the sand is in the conduit, just blowing air through the pipe
isn't going to magically elevate the sand particles 1ft or more in the
air. The air does not have sufficient mass to convey enough momentum
to move the sand particles, much less eject them vertically. For
that, one needs a denser medium, such as water. Shoving a plunger
through might work, but it's equally likely to jam sand particles into
the PVC conduit walls.

Not surprisingly, that's what E&M texts say too--or leave as an
exercise. With a larger diameter, there's less net magnetic field for
a given current, so less energy stored, so less inductance.

Cheers,
Tom

> Lest there be any confusion: an antenna IS a transmission line.
>

Hello, and I think one would have to include two antennas and the intervening medium(s) for the above statement to make sense. In any event, the behavior of an antenna-medium-antenna as a passive 2-port device can be considered as a transmission line at a given frequency. The "loss" associated with this topology can be mitigated by keeping the two antennas within a near, rather than far, field separation. Over a range of frequencies the behavior of this 2-port can easily differ from that of a transmission line, though.

In some electromagnetics textbooks an antenna is developed mathematically via the gradual unfolding of a twin-lead transmission line. And many hams know that a quick and dirty dipole can be created by simply folding the braid back on a length of coax so that the braid and the exposed center conductor become the radiating elements.

A more correct statement might be that a transmission line can be an antenna. This can include unintended radiotion (e.g. RF flowing on the outside of caox due to imbalance and/or stray coupling) or intended such as Andrew's "Radiax" brand of leaky transmission line for installation in tunnels and elevator shafts as a convenient means to extend the reach of over-the-air broadcasts. I thought that the inductance tends downward as the diameter of the wire
increases. I can understand your calculation after the wavelength part,
but don't quite get the increased inductance part.

It can work, because what you are trying to do is not to move a lot of air and sand, but try to make some noise. And you don't have to move a whole lot of sand to do that. As long as the pipes stay together, some air will make it out of the open end and make some noise.

exercise. With a larger diameter, there's less net magnetic field for
a given current, so less energy stored, so less inductance.

Cheers,
Tom

So, then, it isn't intuitive (to me, at least) that a fat antenna has more
inductance. Intuitive to me is that the reverse may be true.

Cheers to you, too, Tom.

John

Yes, making noise was key in locating my underground PVC. In my case, I was able to locate the end by listening closely NEAR where I thought it should have been while someone else was running a snake fully inserted in the pvc back and forth a few inches.... the noise it made at the last sweep was evident with no other background noise to interfere with it.

Mike, N3LI wrote:

Good observation.

Wire inductance decreases with the circumference increase as this effectively places more parallel inductors in place along the surface of the wire.

Wire capacitance increases proportionally with the square of the circunference of the wire as it is proportional to the wire`s surface area.

The fatter wire grows capacitance faster than it changes inductance.

Reactance along a wire antenna element varies quickly near resonant and antiresonant points so is not uniformly distributed. This complicates calculations and requires average values for some. Bailey says of surge impedance: "Nevertheless, this variation in theoretical surge impedance shall not deter us from setting uup practical "average" values of surge impedance.

If B is the 'phase velocity' then surely it's also the 'velocity of phase propagation' so that's not 2pi/B? The velocity of propagation of an electromagnetic wave, be it the phase or group velocity, is most-strongly dependent on the permittivity and permeability of the medium in which the wave is propagating.

Another clue to resolution of this issue is that the terminal impedance of an open circuit stub has a slope with respect to frequency that depends on the characteristic impedance of the stub. For the case of a cylindrical dipole, the characteristic impedance is not constant but increases progressively along the lengths of the limbs, but the slope of the terminal impedance can be related to an 'average characteristic impedance' and the value of this parameter depends on the average distributed inductance and capacitance, as has been said here before. Z = sqrt(L/C) in general terms.

The self-inductance of a conducting cylinder has been shown fairly rigorously by some (e.g. Rosa, and used by Terman) to be inversely proportional to its radial 'thickness' but this appears to be a contentious issue and can lead the unwary user into a paradox!

A good rule of thumb for small gaps with large radius of curvature
electrodes is 30kV/cm (e.g. a 1cm gap between 10cm diameter spheres).

In strongly non uniform field gaps (e.g. needle gaps), the breakdown is
typically 1/3 or less.. that is, 10kV/cm

70kV/inch or 25 kV/inch, respectively.

A sparkplug with a 0.035inch gap would breakdown around 1-2kV in normal
air. In an engine, where the density at firing is probably 5-10 times
higher, the voltage is 10-20kV as you've given.

The usual way to set spark gaps for this kind of thing would be to make
it adjustable, fire up the transmitter at worst case max power and
reflection, and set the gap to be somewhat bigger than causes the gap to
break down. A good worst case would be 2x peak RF voltage (i.e. 2.8

Vrms), since that's what you'd get with a 100% reflection at just the wrong phase. (unless the source can supply reactive power.. then it's a lot more complex, because of the potential for resonant rise) You could use a current limited DC power supply or something like a neon sign transformer to set the spacing.

But making things practical..

say 2 kW and a 450 ohm transmission line. Erms = sqrt(2000*450) = about 950Vrms.. call it 1350V peak. With sharp ended electrodes (like the sheet metal V shapes shown in old ARRL handbooks) one might want a spacing of 0.050 inches?

> whether that value is the magnitude of the impedance (which correlates
> to SWR) or the real part of the impedance (since the tuner should be
> able to cancel out the reactive part of the impedance). W0BF

Firstly, it should be noted that the magnitude of the impedance (Z) does NOT correlate to SWR. As a matter of fact, the formula giving SWR as a function of resistance (R) and reactance is such that R-X pairs corresponding to the same Z magnitude may well yield different SWR figures and, conversely,.R-X pairs yielding the same SWR figure generally correspond to different Z magnitudes. This can be readily visualized on the Smith chart.

For instance the pair R=30 ohm, X=40 ohm yields an SWR of 3, that is the same SWR produced by the pair R=150 ohm, X=0 ohm, despite the two Z magnitudes are different (50 ohm in the first case, 150 ohm in the second one).

That said, an excerpt of the MFJ-993B autotuner manual reads: "... it is rated at 300 watts to match 6 to 1600 ohms antennas (SWR up to 32:1)"

In my opinion, as a load of 1600 ohm would actually yield an SWR of just 32, the MFJ sentence makes reference to a pure R of 1600 ohm (that is with X=0). As a matter of fact, a Z magnitude of 1600 ohm, if not purely resistive, could correspond to quite a wide range of SWR figures, and not necessarily to 32..

The cited sentence excerpt then tells nothing about the tuner ability to neutralize the reactance of reactive loads.

On the other hand one must consider that, for the sake of limiting the internal switching arrangement complexity, automatic tuners usually adopt an L-type network in which the reactive element connected at the antenna (either in series or in parallel, depending on whether a step-up or a step-down transformation of the R is required) is not switcheable, i.e. it is either an inductor or as a capacitor. This means that a tuner may inherently be more tolerant of capacitve loads with respect to inductive loads, or viceversa, depending on the way it is designed.

Bruce,

Where an impedance range is loosely specified as you quote (dimensioned in ohms without identification of the R and X parts), and in the absence of applicable frequency constraints and loss figures, I think you can safely disregard the information as unprovable advertising hype.

It is intended to look technical, something to impress the new wave of hams who don't have the understanding, and not enough to reliably determine the suitability of the ATU to a specific application.

Owen

It would appear your first sentence is contested by your last sentence
in your reply. It follows, then, that changing my statement through a
speculative inclusion introduced a problem not already in the
original. When we withdraw your inclusion to suit your complaint, we
are again left with my original.

What you are arguing is a failure of application, not a failure of the
device. I've seen similar arguments that forced terms of transformer
or transducer into the mix to show how they fail. I find the terms
suitable in a casual discussion, but the new minted failures occur on
the basis of forcing definitions when the casual applications worked
just fine.

One can, by a simple twist of the oscillator's frequency knob, find
failure in all analogues of antennas, lumped circuits, and
transmission lines. Those failures are not exotic perturbations in
the 5th decimal place, but simple and utter refusals to conform to a
general rule (such as my bald statement). For any attempt to refute
my bald statement with "proven concepts" will reveal those challenging
concepts built on a foundation of sand by a similar token of counter
proof.

And where is the air going to escape? He said he duct-taped the end shut. With enough pressure, he'll have a blow-out, but that could also result in getting dirt inside the pipe, which I believe wouldn't be good. However, short of that, there's no hole for the air make noise....

He knows the length and direction. He should be able to make an educated guess as where to dig.

Hi D

You and Jeff may know something I didnt realize about sealing. I cant imagine being able to make duct tape seal off the open end of a PVC pipe with tuct tape, How much pressure can be sealed with the tape on the side of the PVC? I would have expected the tape to have been applied to prevent sand from entering. That wouldnt seal against much air pressure. Furthermore, it is very easy to apply only adequate pressure to initiate some air flow , not a sudden blast at high pressure to cause a crater. As you know, a small amount of air flowing thru a small passage can produce plenty of sound.
You are right, he has found the end of the pipe. I am curious to know why it is necessary to write that the air leak method *wont* work when I am sure it will work, Jimmy has demonstrated that.

I know we're talking about linear antennas here, but even in that
case, it's surely not true that capacitance increases as the square of
the wire diameter (or radius or circumference); nor inductance
proportional to 1/diameter. Consider that if both those were true,
doubling the wire diameter would quadruple the capacitance and halve
the inductance, and the propagation velocity along that wire would be
1/sqrt(4*0.5) or about .707 times as great as with the thinner wire.
Clearly things change much more gradually than that.

In the controlled environment of a coaxial capacitor, the capacitance
per unit length is proportional to 1/log(b/a), where a is the inner
conductor diameter and b is the inside diameter of the outer
conductor. If you change b/a from 10000 to 5000 (huge outer diameter,
like a thin wire well away from ground), the capacitance increases by
about 8 percent. Going from b/a = 100000 to 50000, the capacitance
increases by a little over 6 percent. Similarly, inductance in coax
is proportional to log(b/a), so in coax as you change the inner

conductor diameter, the capacitance change offsets the inductance change exactly and the propagation velocity is unchanged. The environment of an antenna wire is different than that, but not so different that doubling the wire diameter has a drastic 30% effect on the resonant frequency.

Cheers,
Tom

I must admit that sand could get into the pipe but I cant see that would be all that bad. My pipe had water in it that is really why I was able to find it. If i want to clean it out I would just blow some strips of cloth through it or in the case of sand rinse it out with water then dry it out with warm air. Shop vacs are great for this. I should have left the damned thing alone. Now my wife wants me to finish putting in the spigot. She gave me a Thanksgiving suspense date.

Jimmie

Well, let's see:

3/4" pipe, and duct tape is usually 2" wide. That means the entire end will
be covered with a single piece with its sides folded down. Duct tape is

designed NOT to let air pass. That means there's a good chance that the seal was air-tight.

3824. 868MHz Propagation problem

Newsgroup: rec.radio.amateur.antenna

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,sci.electronics.design,rec.radio.amateur.equipment

Hello All

We have a propagation issue that is confusing us. We have two 868MHz modules on test, each capable of 500mW transmission.

We are testing to find the range of communication. We are testing them as follows. One remains in our office while the other is taken to the street outside. we are communicating charecter strings such as "Im at the lamp post number 1" etc. There is somebody at each end sending text strings in a continuous conversation. There is no protocol, error checking or error recovery.

What we have repetadly found is that the radio in the office can receive long after the radio in the street has stopped receiving. (The person with the radio in the street is moving away from the office.)

The radios are the same and the power supplies to the radios are the same. Indeed switching the radios gives the same effect.

The propagation paths between the two radios are the same in terms of distance. However the radio signal transmitted from the office travels through walls first before then traveling through open space. Its the opposite for the radio in the street, firstly traveling through space and then through the walls in the office.

We did think we had identified an interfeering source in one direction (when moving away from the office) so we started moving in the opposite direction. We found exactly the same effect.

Are we getting interfeerance from GSM, ISM or Paging?

As far as GSM bands go in Europe 890–915 MHz OR 1710–1785 MHz So these shouldnt be our problem.

ISM is where we intend to operate and the greatest band occupancy should be 10%. So we should get communication even though we would get some interfeerance.

Paging - well this has very much gone out of fashion in Europe. But even if it was the cause then wouldnt it be intermittant communication. We have a constant problem.

Can anyone shed light on this phenomonon? Is it an issue of wireless propagation that Im not familiar with or is it Interfeerance?

Best regards, and thanks for any input.

Denis

You may experience receiver desensitization from a strong out-of-band interferer which is not penetrating well into your office and hence not interferring there.

<snip>
Hello, Richard, and all. And as I previously pointed out the 2-port model might not be the equivalent of a line in a broadband sense. Another way to put it would be that the 2-port could have the electrical characteristics (characteristic impedance, delay, loss) of a particular line at one frequency but of a different line at another frequency.

Please excuse my snipping of the remainder of your comments but they sound more of philosophy than science and quite frankly I have no idea what you're talking about. You emphatically stated an antenna "IS" a transmission line without a few words on why this should be so.

My take on a transmission line (or waveguide) is that it is a medium (ideally lossless) used to convey electromagnetic energy from one place to another. An antenna (or antenna array) is used to introduce or extract electromagnetic energy from a medium. Unlike the power available at the output of a low-loss transmission line, a receiving antenna operating at a far-field distance from a transmitter can only extract a macimum of 1/2 the power available from an incident electromagnetic wave.

Now, if you meant that antennas and transmission lines share phenomena in common (e.g. standing waves) that would be a correct statement. And Maxwell's equations certainly apply to both. But I don't see an equivalency of a single antenna and a non-radiating (at least intended by

design) transmission line and I don't recall any of my many
electromagnetics texts making such a statement. Sincerely,

The matching range of a typical tuner can be estimated
by playing with the simulated tuner at:
http://fermi.la.asu.edu/w9cf/tuner/tuner.html
Select the frequency and load needing to be matched,
click auto, and see if the tuner can match it.

I wonder if Kevin would be interested in making the
tuner's CLC values user specifiable?

I have modeled tuners with Microsmith (an old DOS
program) and varied the C1, L, C2 values while watching
the trace on the Smith Chart. Given all possible
combination of CLC values, the result would be the
matching envelope of the tuner at a specified frequency.

What would be nice is a program that would automatically
plot the tuner's matching envelope on a Smith Chart given
the input parameters.

Hi Guys

Thanks for your input on this.

The idea of height being a problem is interesting. The radio in the
office is on the 1st floor (i.e above the ground by one floor).

If the antenna were at the same height would the problem go away?

We will test and see

higher antennas = longer range. Thats your issue.
Also lack of error correction, poor antenna pattern to meet the low
power regulations, and a less then robust protocol, ie your probably
using some form of on/off modulation where the receiver does not have
a continious wave signal to locl on and track. Try sending a preamble
character that is 10101010 a few times, assuming your receiver is
sophisticated enough to use AGC. This sets the DC level in the
discriminator more accurately and reduces errors.

your using a radio with intentionally designed in limited range to
allow reuse of the frquency.

Steve

What we have repetadly found is that the radio in the office can
receive long after the radio in the street has stopped receiving. (The
person with the radio in the street is moving away from the office.)

The radios are the same and the power supplies to the radios are the
same. Indeed switching the radios gives the same effect.

Is your office in a concrete building? Or one with any steel reinforcement
or steel or aluminum studs? If so, it could well be that there is a
standing wave issue, so that a portion of your transmitted signal is being
reflected back, and so not making it to the receiver. This would not
necessarily affect the reception on the radio in the office from the outside
radio.

The radio outside is likely being desensitized by some other signal.

I see you have other responses. One test that would establish that is environmental (adjacent signal, receiver desense, etc), if BOTH units could be moved to a relative RF free environment such as a rural setting and then test the range.

If this eliminates the problem, then its probably time to break out a spectrum analyzer and take a look at what is around your operating frequency.

Andy

It's because the paths are not the same. Think of a silvered mirror. It can transmit light much easier in one direction than the other. Take both outside and see if it has the same problem. (extremely doubtful because the path's is virtually identical)

Did you design the receive software?
Or did buy the receiver "off the shelve"?

Perhaps there is a problem
with the receivers and how they are
receiving the data.

um, did you read his message? He said that it was independent of the
receiver because they exchanged them and the same problem. i.e., it helps to
read the original post.

Trying to make a "readers Digest" version here....

If I'm following so far:

The lowered frequency of resonance is due to changes in the velocity factor.

The lowered vf is somewhat due to increased capacitance, and an increase in inductance - the latter part I'm still trying to grok. I think there is likely something more going on.

I'm still left with the increased bandwidth phenomenon. None of the above would seem to account for this.

I've been working with mobile antennas for the past several months, and I might be going astray, because I keep thinking about increased bandwidth as a partner of lowered efficiency. Not likely the case here.

Thanks to everyone for the help, while I'm happy to accept the obvious real results, It is even better if I can understand what is going on.

Absolutely, such as two antennas stuck into a superconducting media,
which extends in all directions to the point of seemingly infinite
distances.

A rather unique way of viewing the phenomenon, and rarely presented in
such terms. Yet, quite valid, nonetheless.

Congrats!

That's probably the best answer, as you are going to fish something or not and it's always more expedient to use the most handy tool first before hauling out the hardware store or the drawing board. This is how it usually plays out, that there is plenty of noise when you are trying to bang the fishtape past the 90's. This is how I learned to use 45 degree sweeps and pull boxes at every opportunity. Anything to avoid the frustration of breaking wire or fish tape and wasting my own time.

>What we have repetadly found is that the radio in the office can
receive long after the radio in the street has stopped receiving. (The
person with the radio in the street is moving away from the office.)

You don't say if you are using the same antenna on both ends, but the environment is very different at each end. Consider that Transmitting is about putting signal into an area, while receiving is about capturing the signals in near field of the antenna, then discerning the intellegence. You would have to analyze the output to be sure, but it may be localized reflections, shading or noise at the street level. Because of this it is so difficult to quantify range. There is equipment and software specifically designed to do what you are trying to do but it is expensive. The result is highly detailed signal strength graphic output overlaid on 3d mapping for each fixed site at various frequencies. Most commercial antenna sites have gone to great expense to generate those maps in order to show what their tower does because it is very different for each location.

Is the moving station manually portable or is it mounted on a vehicle?

If the moving operator is bored and continuously talks on a GSM phone
or if the (vehicle) generates some other kind of interference, this
would reduce the SNR at the moving station.

Does the transmitter have some kind of SWR protection ?

If the Tx antenna is close to the wall, it might detune the antenna,
increasing the SWR and the SWR protection drops the transmitter power.

There used to be a ham near me that use an auto tuner to feed a
doublet. I dont think the antenna was cut for any particular frequency
just the most wie he could get strung from corner to corner of his
yard. He found he could get it to tune up on all the HF bands but only
by changing the length of his feedline between the tuner and antenna.
I was thinking it may be nice to have a tuner that could control an
external relay to switch in/out custom networks for adapting it to
site specific operating conditons.

No to all of that... the changes in apparent C and L are a poor
model.

Consider that each little section of the antenna has a EM field that
interacts with each other section. Say you sliced the antenna up into
little strips lengthwise, and measured the inductance of one strip by
itself and then measured the inductance of all in parallel. If the
little strips are "far away" from each other the inductance will be
less (i.e. 1/Nstrips)... but they're not "far away".. the field from
strip 1 couples to strip 2. So there's a nonzero mutual inductance you
have to take into account. You need to calculate the M between strip 1
and strip 2 and strip 3, etc.

Same thing applies to capacitance. There's a capacitance of each
little chunk of the antenna to the surroundings. There's also a
capacitance to adjacent chunks. And to chunks that are 1 chunk away.
So, you can't just say.. I know the C of one long strip, and there are
N strips, so the C is N*C..

In the case of an infinitely thin wire, you CAN make some simplifying
assumptions AND use some analytical approximations (i.e. the
inductance between a segment of an infinitely thin filament and
another segment is well defined, so you integrate over all segments,
which are themselves infinitely small).

There's also the propagation speed issue. Say you slice the antenna
up crossways (like a salami).. there's a L and a C between each slice
(i.e. N^2 Ls and Cs for N slices), although it's symmetric, M12 =
M21. If you put a changing current through an inductor that has some
mutual inductance with another, then some current is induced in the
other. However, since the antenna is a significant fraction of a
wavelength long, there's also a time delay involved, so that current
occurs a bit later. That is, the change in current in segment 1
induces a current in segment 2, but delayed by the distance from 1 to

2. Segment 1 also induces a current in segment 3, but it's delayed
even more.

So, rather than some simple model of a single L & C, or even a simple
distributed LC transmission line, you really have a model that has
lots of pieces, each connected more or less to all the other pieces by
some factor (which includes a time delay).

ANd this is what programs like NEC do. They actually divide the
antenna up into a bunch of segments, calculate the interaction between
every possible pair of segments (making some speed up assumptions for
segments that are very far apart), and then solve the system of linear
equations that results. You can get an arbitrarily accurate model by
making the segments ever smaller and more numerous, restricted only by
numerical precision and computing time. NEC does make some
simplifying assumptions. It assumes that the current along the segment
is represented by a simple model (a basis function), a constant plus
two sinusoids. I believe MiniNEC simplifies even further by assuming
constant current in the segment. The tradeoff is that for the same
accuracy, the rectangular basis function will require more segments
than the NEC basis function, but, it's easier to compute.

>
> I'm still left with the increased bandwidth phenomenon. None of the
> above would seem to account for this.
>

You're right.. it doesn't, because the simple models don't account for
ALL the interactions between subpieces of the antenna. The formula for
the inductance of a rod above ground doesn't know about propagation
speed, so it deals with the mutual interaction of one piece of the rod
with another, but not the time delay.

Think of it like the breakdown of the DC formula for resistance of a
round conductor as you start running AC through it. The DC formula
(resistivity * length/cross sectional area) doesn't account for
inductance, so when you run AC through, the inductance of one current
filament relative to another starts to have an effect.
> I've been working with mobile antennas for the past several months, and
> I might be going astray, because I keep thinking about increased
> bandwidth as a partner of lowered efficiency. Not likely the case here.

No.. Bandwidth does not necessarily go with lower efficiency. That
statement is often the result of misinterpreting the statement about
size and Q and gain being related. A big fat antenna will have high
efficiency AND wide bandwidth.

wow so many of these replies are wrong..

in almost all cases, RF path losses are RECIPROCAL.

(even a 1/2 silvered mirror is reciprocal to light)

As some have said, the cause of your issue is probably interference to
the outside receiver.

Or maybe something about the indoor setup is causing the indoor Tx to
operate at lower power.

It is very unusual for RF path loss to be non-reciprocal.

Mark

so as the wire gets thicker the C per unit length goes up at some rate
and the L per unit length goes down at some other rate, fine so that
reduces the characteistic Z by some rate....but none of that changes
the wave velocity as was pointed out above in the coax example.

I think the shortening effect may all be due to the extra C of the end
surface, i.e it iss end effect. For a thick wire, the end is a circle
that has C and this is all extra C that is not present for the thin
wire. Is this extra C alone enough to create the shortening effect?

Mark

If I remember my antenna/propagation theory correctly, such a change should affect both the transmit and receive gains equally. That is to say, if moving the office antenna lower will reduce its transmit range, it will also reduce its receive range.

What you are looking for is something that is reducing the office end transmit power while leaving its receive sensitivity intact. Someone else suggested an SWR problem due to near field interference with the antenna.

Most likely scenario.

Also make sure that in your design you are powering down the transmitter
fully in the receive mode. In some radios there can be a residual
carrier from the PLL causing self interference ar interference to other
nearby nodes.

Well that guy is usually on a differet page.

> As some have said, the cause of your issue is probably interference to
> the outside receiver.

That's what I think is the most likely cause. The guy outside probably has
his Nextel phone with him. ;-)

> Or maybe something about the indoor setup is causing the indoor Tx to
> operate at lower power.

I suppose that's possible too. The OP should make sure the power supplies
are equivalent (meaning that the output power would suffer more than the
receiver gain with a drooping supply). So check the indoor supply.

For the record, I duct taped the end well, when it was initially buried, in order to keep out sand and even water. It was applied well enough to prevent any reasonable air pressure from moving it, in my opinion. Duct Tape is awful sturdy stuff, and sticks quite well, too.

As I already said earlier, a bunch of you guys posted some excellent ideas I could have used.... and I probably would have if my first simple try with making noise with my fish tape hadn't worked.

Thanks again to all.

The reactance of a conductor with a relatively large cross-section changes
slower with a change in frequency than one having a small cross-section.

Therefore its impedance bandwidth remains below a given limit over a greater
frequency span than one of a smaller cross-section.

Why even have a tuner if you are going to switch the length
of the feedline?

http://www.w5dxp.com/notuner.htm

In my Arizona implementation of this antenna, I used
relays driven by a 80C51 microcontroller to achieve
an autotuner function.

If you plot the feedpoint Z over frequency as R and X on a
rectangular scale (not a Smith chart), you get a spiral. thin
antennas have a big spiral crossing the R axis at X=0 very steeply
(implying narrow match bandwidth), while fat antennas have a smaller
diameter spiral.

As someone else has pointed out, the spiral eventually converges to
something like R=377 when frequency is very high.

The "why" for all of this does not admit of a simple explanation.
(thereby providing nice grist for EM textbook writers, and brain
bending work for EM students)
It's the trying to understand why (the actual measured data has been
around for at least a century) is what prompted the work of folks like
Schelkunoff, Hallen, King, and others. They came up with good answers
for very specialized cases (inifinitely thin wires, conical antennas,
etc.). The fact that "real" antennas tend not to look like the
idealized ones with the analytical models led to the development of
finite element methods, in particular, the Method of Moments, which
NEC and it's ilk are based on. The idea had been around for a while,
but fast computers made it possible to do for interesting non-trivial
cases.

There are similar analytic models that are "pretty close" for Yagis,
for instance.

No.
And, "end capacitance effect" is a poor model for what's really going
on. It's been used as an "explanation" for the observation that an
antenna that is slightly shorter than half a wavelength is resonant(as
in has no reactive component at the feedpoint). The problem is that an
infinitely thin dipole is resonant at less than 1/2 wavelength, and in
that case, there's no real "end" to have an effect.

Hi John,

Your statement above is as much a rambling philosophy as you argue I write. The difference is in pride of authorship alone.

>Please excuse my snipping of the remainder of your comments but they sound
>more of philosophy than science and quite frankly I have no idea what
>you're talking about.

We can agree your motivation wasn't to go there. Some little portion of this is going to be about that motivation.

> You emphatically stated an antenna "IS" a
>transmission line without a few words on why this should be so.

Again, a contradiction. You note my brief statement, and then you complain of length - "without a few words" which is as archaic a construct as any I've employed. In light of charges of rambling philosophies, I enjoy irony too. It is very hard to answer a "damned if you do, damned if you don't" rebuttal, so I pursue your semantics that invite their focus.

>My take on a transmission line (or waveguide) is that it is a medium
>(ideally lossless) used to convey electromagnetic energy from one place to
>another. An antenna (or antenna array) is used to introduce or extract
>electromagnetic energy from a medium.

A transmission line is not a medium in the strict usage of the term medium. Terms are important, or they become your own philosophy. The ï¿½ther fully qualifies under your application and it is multiport beyond count. So, predictably, this medium you speak of fails upon the basis of exhibiting more ports than is necessary.

Perhaps "fails" is too strong, but it is enough to note that your inclusion stumbles against your premise at the top of this quote.

>Now, if you meant that antennas and transmission lines share phenomena
>in common (e.g. standing waves) that would be a correct statement.

I generally write what I mean. I take responsibility for it. If
there is doubt, then a question offered will erase that in following
rounds of discussion. Volunteering tea leaves reading only adds to
the murk.

>And
>Maxwell's equations certainly apply to both. But I don't see an
>equivalency of a single antenna and a non-radiating (at least intended by
>design) transmission line and I don't recall any of my many
>electromagnetics texts making such a statement. Sincerely,

That is why I offered three sources (posted twice in this thread) that
speak to the matter at great length and with enough elaboration in
math to resolve problems of what you complain of in my "philosophy."

So, as popular culture maintains that "the third time is a charm":

I am happy to parse philosophies expressed here, but a visit to the
PTO would serve informed discussion far more. Schelkunoff expressly
chose to extend the transmission line into antennas for a very good
reason, and that reason has served conventional antenna design quite
well.

Hi Mike,

Only if you think of the vehicle body as the fat radiator and the
"mobile antenna" as a tuned radial. Unfortunately, that tuned radial
restricts the capacity of the fat radiator to achieve wide band
operation. Wide bandedness is a function of the complete system.
Unfortunately most look at the "radiator" and miss the necessity of
the counterpoise which demands an equally "large" contribution.

It is assumed that the path to and from the office should be inferior
to the line of sight path out on the street. This may or may not be
true. The building may actually be offering gain in certain
directions. I would start by seeing if the same condition existed at
many more locations. If it does then other ideas need to be examined,
I would start by examining the RF environment outside the building.

A very good description of the symptoms and relations.

>We did think we had identified an interfeering source in one direction
>(when moving away from the office) so we started moving in the
>opposite direction. We found exactly the same effect.

A good test for reducing variables. If you identified an
interference, I would presume you could do that again in the other
direction.

>Are we getting interfeerance from GSM, ISM or Paging?

Only if the remote set was nearer to an undiscovered interferer. You
seemed to have resolved that once, and you should be able to detect
the similar occurrence again.

>As far as GSM bands go in Europe 890ï¿½915 MHz OR 1710ï¿½1785 MHz So these
>shouldnt be our problem.

This is a flaw in the logic. Your frequency of operation is very
close to these bands - unless your sets have been designed with

elaborate front end tuning (which seems unlikely).

>Can anyone shed light on this phenomonon? Is it an issue of wireless
>propagation that Im not familiar with or is it Interfeerance?

One component not discussed is the remote set's proximity to the operator. The operator could disturb the local field (aka shield). Going beyond is the effect of a Fresnel Zone, but your descriptions describe a complete black-out. To test this requires you to go further away to see if you pick up the signal again. This is a long shot, however, as the effect would be distinct within the space of a meter or so. For mobile operation, the Fresnel Zone creates what is called "Picket Fencing" as the signal comes and goes quickly with distance traveled.

Perhaps it is the proximity of a Pub, and your operator stopped in for a Guinness.

Because it would require only one external switch, be useful on random
lengths of antenna, probably a few more I could think of if I didnt
have to get to work.

Yes. I believe the radios and antennas were exchanged with the same results. So, even if separate frequencies are used in opposite directions, the impaired direction, which was reported as unchanged, indicates something wrong with transmission not reception at the fixed building location. Any street location seems deaf. Perhaps there is interference up and down the street.

Best regards, Richard Harrison, KB5WZI

I'll second Pere and Anthony. Strong out-of-band signals is what I found mostly in situations where path losses seemed strangely non-reciprocal.

Post a schematic. One possibility is that your receive input filter is wide open like a barn door and GSM swamps the receiver.

Another option if you have a spectrum analyzer: Hang a large near-field probe into a long cable, tape it to a broomstick and hold that out the window for a while. See what pops up on the screen. If this is in a city be prepared for some commotion among the pedestrians down there :-)

Hey:

My crystal balls are saying:

Multipath where a reflected signal from the source
is being cancelled out in the zone sort of like
standing waves. It's like waves in a bath tub
they bounce of the sides and produce more inter-
ference waves, and so on. Or FM broadcast stations
signal in the big city with tall buildings, all of a sudden
the signal just goes puff while you're driving along down-
town.

I'd say gits your antenna near a window or put up an
outdoor antenna.

377 ohms is the impedance of free space, which is the ratio of E to H fields of a planar TEM wave. People keep looking for this value when dealing with antenna impedances, apparently due to the common misconception that antennas are "transformers" of some sort to "match" the impedance of free space (an E/H ratio) to a transmitter impedance (a V/I ratio).

Quite a few people have tackled the problem of the impedance of an infinitely long dipole. In _Antennas and Waves_, King & Harrison conclude (p. 234) that the impedance is approximately 214 - j189 ohms. However, this requires extrapolation from calculated and measured results, since convergence is extremely slow. In _Antennas_, Kraus's analysis doesn't show convergence, but it's based on a simpler theory which I don't believe is as complete. Because it's not of much practical interest, most of the analyses appear in academic papers rather than antenna textbooks. It's not at all a trivial problem.

?? I have been under the impression that in the limit as the
conductor radius goes to zero, the resonance does go to a freespace
half wavelength. You have to make the antenna _really_ thin to get
anywhere near that, though. Even a million to one length to diameter
ratio won't do it.

There's another empirical point, though, that may be worthwhile
considering to convince folk that Jim's exactly right that you can NOT
just figure things from "capacitance" and "inductance" and the
resultant propagation velocity. For the resonance of a nominally half-
wave dipole in freespace, the resonance changes by only a small amount

as the wire becomes thicker. With the wire length/diameter ratio at 10,000:1, resonance is about 2.5% below freespace half wave. For l/d = 1,000:1, it's about 3.7%. At l/d = 100:1, it's about 6.1%. But for the same l/d ratios operated at full-wave (anti)resonance, the factors are respectively 7%, 9.3% and 17.5%. It would be tough to reconcile that difference using the simple L and C per unit length model.

Ronold King made a career out of developing the theory of linear antennas. I find the "Antennas" chapter he wrote for "Transmission Lines, Antennas and Waveguides" to be a valuable source of insight about antennas. It's presentation is more empirical than theoretical, but I've found that his explanations there pretty much always give me better insights into what's going on. It can be tough to find the book, but I do have a PDF photocopy... If you want to get seriously into the theory and math, one of his other books might be just the ticket. Though I like the way he presents the material, I know of others who are turned off by it, so "ymmv" as they say.

Cheers,
Tom

OK, thanks again for all the good advice. After concidering all the
suggestions and re-reading 3 different ARRL antenna manuals I have
decided to go with a buried cable (uninsulated of course) all around
the house and extending out to my vertical antenna base. I will run
ground straps from the electrical service box, my bedroom receiver,
and the entrypoint for my feed lines to the buried cable. I am going
to go with the spark plug (non resistor type) protection combined with
knife switches to disconnect the rig -and- ground the ballanced
antennas to the buried cable. All co-ax will have commercial gas type
protectors grounded to the cable. There will be a copper bus on the
back of the shack bench with -all- gear grounded through it to the
buried cable.
I will also put spark gaps on the base of the tower grounded to the
cable. There will be a large expensive surge protector in line with a
power distributing strip on the bench which will be unplugged at the
first indication of electrical storms.
The inspiration for all this is a large Oak tree out back with the top
15 or 20 feet blown off by a lightning strike.
If there is anything I have missed please call it to my attention.
Thanks Gary N9ZSV

Not too tough. Amazon has 7 copies from $9.96 -
http://www.amazon.com/gp/offer-listing/B000V097D0/ref=sr_1_olp_8?ie=UTF8&s=books&qid=1224901677&sr=1-8
They appear to be the original 1945 hardcover book. Mine is a soft cover
Dover reprint published in 1965. Alibris has 17 copies, for $7.00 up -
http://www.alibris.com/search/books/qwork/6788112/used/Transmission%20lines,%20antennas%20and%20wave%20guides.

The quick web search that found these also found others. I picked mine
up at Powell's some time ago for $15.00.

I also highly recommend this book.

In regards to non reciprocal operation, the only time I have ever
experienced this during LOS communication was during some form of
interference . Most recently this took the form of a pair of UHF
telemetry transceivers where the local end worked well with 5 other
remote transceivers but not with one at one particular location. it
turned out to be caused by an oscilator in some equipment used in a
nearby business. Normally the oscilator was keyed of and on when the
equipment was used but for a few weeks it had been constantly keyed.
Apparently this did not effect the operation of their equipment.

That duct tape isn't at all likely to seal the pipe; some air will
escape - One of the reason's we don't repair flat tires with duct tape.
8^)

As an example of sound traveling underground, here in the
battleground state of PA, there are a lot of places where there are
streams underground. A tiny trickle of water can be heard even by my bad
ears, several feet underground.

Good reason. How many variations of feed line length can you have?
Enough to handle all the frequencies you might want to use? Possible,
but that's a lot of switches/switching. Oh well, a tuner just seems
simpler.
I gotta do that 'four letter word' too...

Half wavelength of zero radius has a feedpoint impedance of about
73.1+j42.5 ohms
(see, e.g. page 639 of Orfanidis's online electromagnetics book
(chapter 16), which gives a one page derivation)
(http://www.ece.rutgers.edu/~orfanidi/ewa/)

Roy's right about the spiral not converging to 377+j0.. I misread the
graph.

I believe the "misconception" is that the E/H fields induced by the injection of an electromagnetic signal into the media (ether) ARE the properties of the ether; I don't believe they are.

Rather, these fields are only the effect of the affect ...

in almost all cases, RF path losses are RECIPROCAL.

(It is very unusual for RF path loss to be non-reciprocal.

Mark

I agree. But, one thing that should be proven is that both modules
are working as intended. The one being used for the remote
application *could* be defective. Swap modules and see if the
receiving problem also switches locations, or remains the
same.

Hello,

There should be a reciprocal relationship between the modules
regardless of height, antennas etc. as long as TX power and RX
sensitivity of the modules are the same (which they appear to be).

The modules are unlikely to have very good input filters at 868MHz, so
any adjacent channel interference (GSM etc.) is likely to cause the
out of balance behaviour.

Try heading in a different direction outside, or go somewhere else
with your experiment.

For your real world application, are you likely to have any site close
to adjacent channel transmitters (cell or broadcast) ? If so, think
about a decant front end filters. This could be costly, but might save
you...

Regards,

Mark

news:159dee31-5436-4f46-ae9d-48214eec09ca@k37g2000hsf.googlegroups.com...
Hello All

We have a propagation issue that is confusing us. We have two 868MHz
modules on test, each capable of 500mW transmission.

We are testing to find the range of communication. We are testing them
as follows. One remains in our office while the other is taken to the
street outside. we are communicating charecter strings such as "Im at
the lamp post number 1" etc. There is somebody at each end sending
text strings in a continuous conversation. There is no protocol, error
checking or error recovery.

What we have repetadly found is that the radio in the office can
receive long after the radio in the street has stopped receiving. (The
person with the radio in the street is moving away from the office.)

The radios are the same and the power supplies to the radios are the
same. Indeed switching the radios gives the same effect.

The propagation paths between the two radios are the same in terms of
distance. However the radio signal transmitted from the office travels
through walls first before then traveling through open space. Its the
opposite for the radio in the street, firstly traveling through space
and then through the walls in the office.

We did think we had identified an interfeering source in one direction
(when moving away from the office) so we started moving in the
opposite direction. We found exactly the same effect.

Are we getting interfeerance from GSM, ISM or Paging?

As far as GSM bands go in Europe 890&#65533;915 MHz OR 1710&#65533;1785 MHz So these
shouldnt be our problem.

ISM is where we intend to operate and the greatest band occupancy
should be 10%. So we should get communication even though we would get
some interfeerance.

Paging - well this has very much gone out of fashion in Europe. But
even if it was the cause then wouldnt it be intermittant
communication. We have a constant problem.

Can anyone shed light on this phenomonon? Is it an issue of wireless
propagation that Im not familiar with or is it Interfeerance?

Best regards, and thanks for any input.

Denis

What is the modulation type and data rate? Could be a delay spread issue. Maybe the outside unit is receiving a reflected signal from the surface of a nearby structure and is experiencing inter-symbol interference that by chance the base unit is shielded from. This would occur only if a high symbol rate was being used.

Nah, that's ok. Every one of us occasionally runs into an unusual
situation. Then one can either stew on it for days without getting to
the ground of it, or ask. IMHO it is a sign of maturity if somebody has
the guts to say "Hey, guys, this problem here really has us puzzled".

That is especially true for EMI cases and this sure looks like one.
Sometimes a brief hint by someone who has been in the trenches for
decades can get things going again. And most older ham radio operators
had that exposure, fixing the neighbor's electronics because their
manufacturers messed up.

The OP said that he did that, and the problem remained. It's certainly a desensing problem due to local interference at one end. That's the only possible cause.

I understand all that. I am however getting the feeling that we don't understand just "why" that happens.

One little thing in my situation, we're about 1/3 mile away from the
Pacific North West Ocean surf and believe me, it is genearlly quite
loud.... enough to preclude hearing delicate sounds in the soil at times.
It took a relatively quiet day just to hear the fish tape rattling.

Internal tuners are limited by size.
My LDG and MFJ 949 do have much greater range than my internal tuner.

I consider the internal tuners to be a convenience for use on fairly well matched antennas. Many serious multiband antennas requiring a tuner benefit from a remote tuner to keep coax losses at bay and disable the internal tuner. I built the LDG 11 kit (no longer available) into an ammo can for automatic remote tuning. I hear the price on the current production remote box is still decent.

Even great big wide range manual tuners can get stumped by impossible matches. Those that seem to be able to, risk arcing or burning components.

Hello All:

I believe there was a posting here or maybe even in QST that talked about problems with Radio Direction Finders in aircraft and ships before WWII time frame. And the fix to repair them so that the Radio Direction Finders (RDF) did not point 180 degree's the wrong direction.

I am researching information on the WWII Aviation Rescue Boats, (AVR's) 83 and 104 Ft long, Boats used by the US Army during WWII.

I spent 5 years on a 104 AVR Boat, converted into a Commercial Fishing Boat for Albacore Tuna from 1966 to 1970 as a teen ager.

Any information would be greatly appreciated. Thanks.

Here's a link that shows some of the AVR Boats and spec's.
http://www.warboats.org/crashboat.htm

Which one?
<http://www.angelfire.com/space/proto57/rdf.html>

Search Google for "sense antenna". This is a 2nd antenna that is used
in conjunction with a loop or Adcock type antenna to skew the pattern
on one direction, thus eliminating the 180 degree ambiguity.
<http://books.google.com/books?id=RfzF2-fHJ6MC&pg=PA237&lpg=PA237&dq=df+sense+antenna&sour
ce=web&ots=OrVQdNKmQ-&sig=lF5RRtEjOoyQ22OPvMEFx3Ljrzg&hl=en&sa=X&oi=book_result&resnum=3&c

a&source=bl&ots=068u54gGNR&sig=3R4XkY8aRiOWMv_cWhCRU94s0JQ&hl=en&sa=X&oi=book_result&resnu
m=1&ct=result#PPA447,M1>

Incidentally, much of the pre-WWII DF work was done from fixed
direction finding stations. A pilot would request location info via
HF radio. Several ground stations would do their best to deliver a
bearing using various types of antennas, with which the pilot would
use to calculate an intersecting position. Gross and inefficient
would be a nice term.

Somewhat later, the "homer" was introduced. This was two wing mounted
forward facing directional antennas. The receiver would rapidly
switch between the two antennas. When the signal level from both
antennas was identical, the transmitter direction was dead ahead. This
worked fairly well, but did create problems for airline passengers as
the pilot flew donuts trying to get a brearing.

Denis,

I agree with some of your previous posts - the outside receiver is likely being desensed by a strong signal, perhaps away from or a harmonic of the frequency you're using. I suggest trying the test away from town and at least 10km from strong transmitting towers. Let us know what you find out - may help those of us who do UHF/VHF mobile/ portable hamming.

As a ham I have NOT PROBLEM with the commercial community asking questions on a ham radio group - we can ALL learn from this.

Cheers,

i was thinking about that...but no....

all the multi-path paths are reciprocal as well,,, so whatever the
delay spread is one way should be the same the other way.

****
I don't know why I don't get the > on your response, but whatever.
He can get some feel for what is going on by taking *both* radios outside
near his office, and walking around. He should be able to find a particular
area that has poor reception. I don't buy the explanations for antenna gain
and multipath, they should affect both directions of transmission equally.

3904. Carolina Windom without a balun: go figure

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-29 00:52:46 UTC
From: jawod <jawod@fuse.net>
Message-ID: <da952$4907b3e0$48316a9a$7867@FUSE.NET>
Source record: 20628

Well, as an update to my Carolina Windom project, I find that the CW OCF dipole cut to typical dimensions works well WITHOUT a balun but does not work at all WITH a balun.

Specifically, a DX Engineering BAL200-H10-AT 4:1 balun. I bought it to go with a folded dipole from DX Engineering. It worked fine with the folded dipole and a length 300 Ohm ladder line as feed.

When I use the above balun with the CW cut to typical dimensions and using a 300 ohm ladderline feed, even RECEIVE is muted...no change from coax only.

I am fairly sure that the balun is a voltage type and not a choke type. I also installed a series of ferrite beads from Palomar to choke the coax near the bottom of the ladderline.

I guess I'm not all that surprised that the CW works without a balun...the ATU tunes it and sig reports aren't bad. I guess I have some radiation from coax and a mismatch from coax to ladderline but I think I can live with that. It's getting cold and I needed to finish this thing before winter really sets in.

I am clueless as to why the CW failed to work AT ALL when USING a balun. The internals of the balun look fine.

Any thoughts?

(here goes)

John
AB8O

Since most of the posts, in their "EXPERT OPINIONS", relate to your receiver being "de-sensed", do you have a way of negating/affirming this?

Begin there, and we can get down to "real problems!" :-) i.e., a wide-band field strength meter, freq counter, etc. will either make all this "right" or "wrong."

Regards,
JS

Hmmm ...

Cecil is the first one to even get me to try an OCF antenna! I thought I like my life "balanced"; now, I find, I can go though live "unbalanced" and "off center." <grin>

However, the 300 ohm line you are using IS balanced. So, I am assuming you have a 50 ohm UNBALNCED output from your rig OR PA, and this is where you would insert the 4:1 (6:1 would be better), and that you have inserted it there, right? Properly, directly at the rigs output, to engage the 300 ohm line, right? (i.e., between the rigs 50 ohm UNBALANCED out and the 300 ohm balanced line?)

If you have it there, and did not notice an improvement, or at least no change, we have another problem--apparently ...

Warm regards,
JS

1. Doesn't the manufacturer of Carolina Windom's claim one of the
benefits is feed line radiation? (If you can't suppress it, call it out
as a competetive advantage?)

2. DX Engineering are a bit light on info on the balun, like most
manufacturers I guess... but the title bar of the web page says it is a
current balun. Pity the technical details tab doesn't make it clear.

3. If the design is intended to excite feed line common mode current,
then the device at the top of the feed line is probably a 4:1 Ruthroff
balun which has very low common mode impedance (differently to an
effective current balun).

4. What has 300 ohm line got to do with the Carolina Windom?

Owen

Desense is definately a possibility, but I still believe that it's at least
AS good a chance that it's a standing wave issue on the office end. Others
have said to take the 'office' radio outdoors and test the setup that way.
That's a good (and simple) test.

3916. HYgain 18-AVT

Harry,
The first thing that comes to mind is an appropriately sized 'heat-shrink' type tubing. Of course, that assumes that you can find such an 'appropriate' size and that it will 'shrink' enough. I have no idea if there is such a size or not.
Another one of those 'off the wall' ideas is to use the stuff that's used in casting small parts in the R/C model hobby. It's a 'rubber-ish' kind of stuff molded/painted around the part, then pealed off when cured and used as a mold for a new part. Don't ask me, I have no idea what it is. No metal content that I'm aware of.
And then, I guess you could always fiberglass it?
- 'Doc

I'm /still/ more inclined towards a desense problem - cities are astonishingly noisy these days throughout the RF spectrum. I've recently had 4.9 GHz data transmission problems that were eventually traced to a harmonic of a nearby surveillance TV transmitter!

Desense caused by out of band signals if of course possible when we
talk about such toy receivers as most wireless LAN or wireless
headphones are.

However, since the 868 MHz band is a non-licenced band, it is quite
likely that there might be other transmitters (e.g. wireless
headphones) in the area of the moving transmitter, but not near the
office transmitter.

Give a spectrum analyzer to the moving station operator to monitor the
interference level in that frequency band, when the moving transmitter
is off. A scanner receiver with a decent signal strength indicator
might even suffice.

>Desense is definately a possibility, but I still believe that it's at least
>AS good a chance that it's a standing wave issue on the office end.

This is out of the question for any single frequency half duplex
connection, since the path would be reciprocal. In a full duplex dual
frequency point to point system between two _fixed_ station, this
would be definitively possible. Even in this case, moving the other
station by 10-30 cm, you would find a spot, in which there is a good
connections both ways.

Based on my experience at 1297 MHz with a narrow band (16 kHz) signal
in urban environment, you definitively have a lot of multipath nulls
(several nulls every meter), For speech communication, this is not
much of an issue, the faster you move, you have hundreds of nulls
every second and it does not much affect the readability of the
speech. The only problem is that if you stop at a traffic light, you
usually will end up in a multipath null and the communication is
broken, unless you can slide the car a few centimeters.

>Others
>have said to take the 'office' radio outdoors and test the setup that way.
>That's a good (and simple) test.

The OP did swap the radios, but he did not tell if the power supply was also swapped. If the office power supply was faulty and the office transmitter could not deliver the nominal power, this could explain the situation.

Paul

I had that problem with a trap beam. I went to a pipe supply & got some end covers that are on pipes when they are shipped. Cut a hole in the middle to fit over the tubing & silicone it on the trap & tubing. Never leaked.

1. Baluns are designed for a narrow range of *resistive*
impedances, e.g. 50/200 ohms (plus or minus). Over what
range of impedances are you asking your balun to function
properly? Baluns don't handle massive reactance very well.

2. A misapplication example: 300 ohm twinlead with a 10:1
SWR can take the impedance seen by the balun down to 30 ohms.
Then the 4:1 balun tries to take 30 ohms down to 7.5 ohms.
That's a lossy situation for a tuner.

Hey John,

Trying to make sure that we are on the same page here.

You are using a OCF dipole with a 4:1 Balun, and using ladder line to go
from the balun to the shack?

Most of the OCF's I am familiar with run coax from the balun to the shack.

What are the respective leg lengths here? Height? Something is a little
askew here.

True enough. I tried an OCF as a way to be able to run coax and have multi band no-tuning and get rid of the window line.

Tried it, it was interresting, and now I'm back to using window line.

Can you use pieces of suitably-large-diameter heatshrink tubing...
pick a piece comfortably larger in diameter than the innards of the
trap, slide it over, and heat it gently with a hairdryer just
sufficiently to shrink it to the necessary size? The safest size to
use would probably start out at roughly 2x the diameter of the trap
guts... it'd be a snug fit when fully shrunk.

Heatshrink tubing is available in multiple colors... I imagine that
some types of the black variety might have some carbon-black in it,
but it's also available in white and other dyed colors which ought to
have pretty good RF properties.

Otherwise, talk to your local general-purpose professional plastics
supplier, and see what kind of tubing they have in stock.

Harry,

I had a 4BTV that suffered failure of the trap covers, a result of
destructive birds eating them.

I made replacement parts from PVC plumbing fittings, not because Hustler
couldn't supply parts, but there was little point repairing with same
fodder for the birds.

The repair is described at http://www.vk1od.net/H4BTV/hustler4btv.htm .
It might give you some ideas.

BTW, Hustler must have seen the article and sent me gratis a set of
original trap covers, they are still in the shed after twenty years...
the PVC works fine and the birds haven't attacked them (though they seem
to enjoy anthing else with exposed PE or vinyl).

Owen

3933. Re: Carolina Windom without a balun: go figure

Source record: 20657

I've attached the original article that describes the CW in question. Three versions of the Carolina Windom are presented: Original single wire feed, OCF with twinlead and balun, and OCF with 10' length of coax to a choke balun (1:1). Mine is the middle one. Please see Fig 3A. The balun is at the bottom of the twin lead (I think I mistakenly referred to it as ladder line). I added large ferrite beads just below the balun on the coax as discussed here in the group earlier.

With the DX Engineering balun in place as in the figure, no xmit and no rcv ... i.e., no diff than open-ended (shorted?) coax.

When I bypassed the balun and connected the balanced twin lead directly to the coax...NOW I have good receive and pretty good sig reports.

Yes a 6:1 balun should also work according to what I've read.

The feedline radiation is intended for the 300 ohm twinlead only, not the coax below the balun.

I am pretty sure the balun is the Ruthroff type that Owen mentions (i.e., not a CHOKE balun)

I guess I'll conclude that the balun has failed. However, on inspection the balun looks perfect...it is only 2 yrs old, has5 KW continuous power rating and I run 40 W. Also, it worked perfectly well when used originally with the DX Engineering folded dipole, also using a 300 ohm feedline. (this is why I chose the CW...I had the stuff for it)

I appreciate the discussion

John

Perhaps the interference is linearly polarized and by changing your polarization (90-deg.?) you can immunize your transmissions.

Thanks Owen,
I guess it was either the Galahs or the White Cockatoos that did the damage.

I know when I used to sell UHF CB to farmers out west, we used to have trouble with them chewing on the top of the collinear antenna.

We used to slide some white PVC down over the vertical and anything over 3/4 to 7/8" in dia used to stop them.

It annoys me that Hygain will not supply them and must get a high enquiry rate for these shields.

I will see if I can find the right diameter and machine them to fit snugly.

Thanks for the heads up on your experience!

Thanks to all those who have offered their advice too.

Yes, I have built radomes from white PVC plumbing fittings to protect
antennas, eg MobileOne's 2m end fed which has a balun made from coax
wound around the outside of the antenna... good tucker for birs.
>
> It annoys me that Hygain will not supply them and must get a high

I have had experience with Hy-Gain, and it was very poor... wound up
making the parts myself... http://www.vk1od.net/VB214/index.htm .

Mindful of that, I limit my exposure to products of the MFJ group.

"Somewhat later, the "homer" was introduced."

The last topic in Terman`s 1955 opus is "Radio Direction Finding". On page 1048 Terman writes: "This behavior (simulated sense antenna) causes a signal to be delivered to the receiver even though the loop ts in the position for zero response;"

I have a friend, N5CPA, who was a B-24 bomber pilot flying out of Italy to bomb Austria and Germany as WW-2 was ending. They had a direction finding station in North Africa to advise them of their positions when needed. Problem was, Germans often answered first with wrong location and direction in impeccable American English so Americans might exhaust their fuel.

Walter Maxwell worked for the FCC at war`s end in Hawaii and equipped himself with an Adcock antenna so he could advise lost American aviators of their positions in the Pacific. I think Walter has published his story in a radio magazine.

Best regards, Richard Harrison, KB5WZI

As you now know, that didn't work.

You need to put the article on a web site somewhere, or give the URL of an existing copy.

Hi Mac,

I know that some animals (eg rats) will eat soft PVC. That motivates cable sheaths impregnated with arsenic... which is worse? We don't have some of the critters that you have, thankfully.

The other commonly used plastic I didn't mention was polypropylene, and I think the trap covers may be polyprop... .

All in all, vermin resistance components, and ready availability are important factors in the life of antennas etc... but we are tame buyers who generally don't consider that until we need to repair the things.

This was the article that convinced me to build a NCW. (The 3rd option)
I scaled mine up to the 132 ft version so I could have 80m.

When I finally have a QTH to support its size, I will string it up
permanently. Till then, it is my field-day antenna of choice.

My 706IIg with AT180 autotuner have no trouble getting a clean match on 6m
thru 80m.

There are a host of issues with the content of the article. I don't intend to red pen the article, but the issues sound a warning about credibility.

There is no doubt it describes a Ruthroff 4:1 balun in its "new Carolina Windom" configuration. Such a balun will have a very low common mode impedance.

Factors of your implementation that are / may be different include:

The DXE balun you used appears to be described as a current balun on the DXE web site. If it is, it may work differently. (I have already commented on the lack of clarity of the product information, perhaps they might clarify it if you email them with a support question - "what did I buy?".)

DXE also warn us that 'tuner' style baluns such as the one you used are more likely to be reactive an higher frequencies... presumably a consequence of thicker wire insulation which increases the Zo of the TL sections which results in less ideal impedance transformation with increasing frequency.

Thanks for the input. The strange thing is that the system failed at
ALL freq's. The original use of the balun was with a folded dipole and
a feedline of 300 ohm twinlead cut to an odd multiple of the lowest freq
desired...which I did and it worked reasonably well. I cannot
understand how this application (the CW OCF) is significantly different
from the original one, at least in terms of using a 4:1 balun.

Allow me to put this to rest. I can live with it as it is, theoretical
considerations notwithstanding. I don't want to go over to the dark
side, but, hey, it works. Maybe I have a new "Magic" Antenna.

A homer is quite different. Dumb story follows.

Once upon a time, the government decided that small business needed to have some of the smaller military contracts directed in their direction. No altruism was involved as the military was just trying to cut costs.

Intech Inc was in the marine radio business and decided to bid on a USCG contract to design and build a homer. The chief engineer handled the negotiations and I only found out after we had underbid everyone else by about 50%. Oops. There was just one problem. Nobody knew what a homer was or how it worked.

After some very strange ideas and misconception, I removed a dusty copy of Radio Engineering Handbook, 3rd edition, by Henney. This is the 1941 edition, but much of the data is from the first edition in 1933 thanks to war time censorship. Pg 613 has a schematic of a homer antenna and receiver system. I drag this to management who initially declares that the USCG couldn't possibly want something that simple. It took a while, but I eventually based the design on the ancient design from the book. It eventually became the AN-SRD/21 homer.

Actually, not a Carolina Windom - simply a traditional Windom, the grandfather of all Windoms - named after Major General Loren G. Windom, W8GZ, (Windy) (QST, Sep 1929, pp 19-22, 84).

www.geocities.com/w8jyz/8GZ.pdf

> OCF with twinlead and balun,

Don't know if it was ever a commercially available antenna called a "Carolina Windom" but this is just a traditional "Off-Center-Fed Dipole" labeled as such in my 1957 ARRL Handbook.

http://www.w8ji.com/windom_off_center_fed.htm

> and OCF with 10' length of coax

This is what most people think about when someone says "Carolina Windom" and the reason that some people were confused.

http://www.hamuniverse.com/k4iwlnewwindom.html

> I guess I'll conclude that the balun has failed.

At least hang a 200 ohm non-inductive resistor on the output and measure the input impedance. I don't know how you can assume the balun has failed if you don't know what impedances the balun was having to deal with.

If I'm reading this correctly, you put the balun at the bottom of the twin lead and the ferrite bead balun just under it.

Many 'Carolina Windoms' use the balun at the feed point, the ladder line or twin lead under that, and the ferrite bead balun at the bottom of the ladder line, to which is attached the coax.

Placing the balun (4:1 or whatever) under the twin lead would really do strange things to the impedance and probably cause the problems you mentioned.

When trying to understand off center fed antennas, it's important to realize a few key facts:

1. A properly working "voltage" or "Ruthroff" balun will force common mode current to exist on the feedline in its attempt to cause equal voltages on the unequal length sides relative to the feedline shield.
2. Even if an effective "current" or "Guanella" balun is used, feedline current will still be induced by the uneven coupling between the two antenna sides.
3. A transforming balun is very unlikely to effect the expected transformation ratio, and is likely to add a significant amount of series and/or shunt reactance except at those spot frequencies where the match is close to perfect.

This isn't to say that off center fed antennas can't sometimes be made to "work", i.e., provide a reasonable impedance match on some bands. But when they do, it's not for the reasons you think from an analysis assuming a perfect transformer and balun. It usually involves a complex relationship among the particular imperfections of the balun/transformer, feedline, and path to the Earth taken by the feedline shield.

Actually, I would expect placing a 4:1 balun under the 300 ohm balanced line and before the 50 ohm unbalanced to provide a step-up(or step-down, depending on the "direction" you view it from) of 50:200 or 4:1, as it properly should. However, as someone presented in a paper a little while back, some antennas "filled with errors" are able to function in some manner and end up gaining their supporters ...

If you were to place a 1:1 balun at this same point, I would expect little difference, but a difference (and, since you are mismatched at this point, simply maintaining this mismatch with a component introducing some loss and "redirecting" CM currents, not a good difference!)

It seems the "misunderstood/mystical/magical balun" lives on ...

Regards,
JS

Yes, I thing you are quite correct Roy.

The advertising hype that goes along with many of these commercially popularised antennas gives the impression that deployment of multi-band wire antennas for the lower HF bands is a very standardised thing, a no-brainer. One buys the product, installs it in their own environment in their own way, and it just "works" out of the box... whatever "works" means.

The real world doesn't work that simply.

But to a buyer with faith in the promotional claims, they can buy a lot of satisfaction for only $69.99 or whatever, and not have any untidy left over materials to clutter up their home, or residual technical issues to clutter up their mind.

Today, the growth opportunity in the US is selling attic antennas for low HF bands to new hams. Not as popular here because restrictive covenants on residential properties aren't as common.

But, hey, a simple wire antenna with published performance figures from 160m to 2m is attractive to *our* new six hour hams. Which antenna is that? The W5GI Mystery Antenna, you know, the one "that performs exceptionally well even though it confounds antenna modeling software".

Scott Stephens wrote:
> Since antennas have reactance and radiation resistance, ...

It might help to note that the antenna feedpoint
impedance is a virtual impedance - a ratio of total
voltage to total current. A dipole is a standing
wave antenna with a feedpoint impedance of:

Zfp = (Vfor+Vref)/(Ifor+Iref) [all phasors]

This type of impedance is covered by the (B) definition
of "impedance" in "The IEEE Dictionary". It is not the
same thing as an "impedor" which is covered by the
(C) definition of "impedance".

Hello,

A small tuned loop behaves as a lumped RLC circuit around the center frequency. Small means small w.r.t. lambda. It has small relative BW (rel. BW = useful BW / Fcenter). It shows lots of ringing. Of course, the model is only valid for the frequency range where size << lambda.

For small loops (especially loops on PCB), most losses are ohmic, just a part of the losses is due to radiation. When you make a good air loop (with air or vacuum capacitor), the Q factor can be over 1000 (so your -3dB impedance bandwidth is very low at HF frequencies). Your VSWR=2 useful bandwidth is about 70% of the 3 dB impedance bandwidth of the antenna.

Thin half wave dipoles can also be modeled with a RLC circuit. The R is frequency dependent, but in a limited frequency range, a simple RLC circuit is useful. When more accuracy is required , or larger frequency range, a transmission line model with lumped losses is better. HW dipoles close to perfect conducting ground have narrow useful BW, hence high Q factor and the RLC model matches better.

Thicker dipoles have wider bandwidth (so lower Q factor). In that case even within the useful frequency range the radiation resistance varies (it increases with increasing frequency). When the Thickness of the dipole (think of a biconical dipole), is in the range of 0.15 lambda or more, Q factor will be that low, that you can hardly see the exponential decaying sinusoidal wave (so it behaves more like a heavily damped circuit).

If you have access to EM simulation SW you might simulate a construction and compare the impedance versus frequency for your LRC equivalent model.

Back to your question, most narrow band antennas are not critically damped and have an impulse response with exponential decaying sinusoidal wave shape. Are you in GPR or equivalent?

Best regards,

Wim

I forgot to say that the surge impedance of a standing
wave antenna, like a transmission line, is quite different
from the steady-state value of feedpoint impedance.

NEC2 doesn't plot anything.. purely text.

And while it can calculate feedpoint impedance vs frequency, which any
number of programs can plot, that's not radiation resistance.

No, they are not critically damped, NOR are they a simple resonator.

>
> Is this implied by a swr plot? Can I take 3db points as antenna
> bandwidth and assume a radiation-resistance loaded-Q from that?

No (this is a common error when folks first hear about the Chu limit and read about Antenna Q. They mistakenly equate Antenna Q with "tuned circuit Q" and then leap to the idea that center frequency/bandwidth = Q.. nope.. Q, in both cases, is the stored energy divided by the energy lost per cycle. But the mechanism is different...)

>
> Does feed-point impedance change radiation resistance?
No. A folded dipole has a feedpoint impedance of about 300 ohms and a dipole has a feedpoint impedance of about 72 ohms, but they have the exact same radiation resistance.

Google for "radiation resistance" and "surrey" to find some pages by Dr. Jefferies at UofSurrey..

http://personal.ee.surrey.ac.uk/Personal/D.Jefferies/radimp.html
http://personal.ee.surrey.ac.uk/Personal/D.Jefferies/antennas.html

With all respect, Owen - a Ham can be just as ignorant if they tested
in the days when we had to mine and smelt our own copper for antennas.

There is plenty of ignorance to go around.

Before I go too much further, Hams should build their own wire
antennas. No excuses.

The interesting thing is that most of these novel antennas work to some
extent. I know a fellow in PA who was excited that he could work Maine
on 40 meters with a really bad antenna setup. He just didn't know what
to expect. (from where I'm at, 100 watts and a modest dipole should just

about ruin an S-meter between those two places)

That is how antenna BS starts. This guy would think that a poor antenna is great because it performs better than his awful antenna.. 8^)

I won't come out and condemn things like OCF dipoles though, because they are an interesting and cool novelty, and by gosh, I had fun building, testing, and using mine. I learned a lot. Used one during Field day, and ran and held frequencies at 100 watts on 80 meters. Totally subjective of course, but low power stations usually don't do that.

One of the things I learned was that it is a real compromise. Higher band performance wasn't so hot. But I'm a lot better off having built it, and finding out it's capabilities and shortcomings, than just believing that it is a bad antenna because I've been told it was so. I know exactly what the antenna is like, and it only took me a few hours of work, and a couple months of testing to find out.

I note this mainly because I am one of the unwashed new Hams - and we aren't all as you describe.

Side note: I was at a Ham supply store this past year, and I was looking
for some window line. They had a dipole antenna that included window
line for about half the price of the same amount of window line by
itself. That's probably the only good excuse IMO to buy a pre-made wire
antenna.

But I don't build my own antennas to save money. I'm trying to learn
something. Can I design and cut and install the antenna, and does it
perform as my design says it does?

> I do build all my wire antennas because

Never built a trap dipole. I'm going to have to try it some day. I guess
the major advantage will be that it won't be so lobey as a longer wire
tuned for the higher frequency. But hey, the experimentation is the fun.

I'm not here to convince anyone that my antenna is bigger than theirs!
;^) he he.

Yeah, I did okay on 80 and 40 too. That was my thing with the OCF. It
just seemed to be at best a 2 band antenna,
IIRC, the bandwidth was a little bigger on my OCF.

All antennas are a compromise of some sort, and the OCF is within the
acceptable range.

3967. "Unwashed" hams and "washed" hams

Newsgroup: rec.radio.amateur.antenna
Date: 2008-10-31 18:40:07 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <2d4e98b7-8d50-490e-a39f-e6dafaa140bc@k36g2000pri.googlegroups.com>
Source record: 20692

I can easily see myself as being viewed as an "unwashed ham" on this
newsgroup !
I am still of the belief that on a fractional wave antenna the current
travels on both the outside
and the inside of the radiator. This puts me in opposition to the
multitude of "washed" hams
who resist change even tho as yet I have not been proved as being in
error.
I suppose a "washed" ham is one who is of the opinion that "all is
known about antennas" and thus
"change" is to be avoided.
At the moment the consensus seems to be that current only flows on the
outside of a radiator as an open circuit where-as a few say the power
jumps from the end of the antennas to ground to complete a circuit.
One would tend to think that a newsgroup of "washed" hams would be
able to supply the definitive answer in line with "all is known".
Points to consider,
A fractional wavelength antenna is NOT in a state of equi;ibrium
(balanced forces if you prefer)
where a full wave radiator IS in a state of equilibrium (balanced
forces where the sum of which equals zero) and all laws are based on a
state of equilibrium per classical physics
Best regards
Art

For some hams, it is cheeper to just buy the wire antennas. By the time you go to the store or order some wire, get the coax, get the insulators, get one or two coax connectors, and maybe a balun , it may be cheeper to just get all in one place for one price. I do build all my wire antennas because I can get the wire for free and found some insulators for nothing. If building trap dioples or other special wire antenas, the parts issue is even greater.

I have an OCF antenna at 45 feet that I use for 80 and 40 meters. It works much beter than an 80 meter dipole antenna at 25 feet usually. They are at right angles to each other. I do have a beam for other bands so do not care how it works on the higher bands. It does seem to have a larger bandwidth than the regular dipole on 80 meters.

As I suspected/feared. If I try to design a pulse generator for a TDR in spice, I'll have to synthesize an appropriate frequency-dependent radiation-resistor.

Perhaps an inverse-Fourier transform of that Z vs. freq plot can give me a time-domain impulse graph?

Yes, I'm interested in TDR and GPR.

Thanks,

Scott, KB9ETU

Looking up the "Chu Limit, I found:
(http://ceta.mit.edu/PIER/pier43/11.0305131.Bellett.L.pdf)

I just skimmed, it seems the mechanism of RLC network is the R, but for
antenna, "Q is formed from the independent contribution of all the modes".

Which, for a UWB or impulse-radar antenna, will be an interesting; a
frequency-dependent resistance to model.

From the paper it seems using a ferrite broadens a loop antenna by
raising radiation resistance across frequencies. Whereas dielectrics
increase energy storage (Q) by confining flux, unlike magnetics.

I've even heard of laser-ionized plasma being used for UWB antenna,
since it will quench to stop it from ringing.

Ed> flat plate we see as the receiver antenna actually radiates

yes it does. Some old design had slotted waveguides and a common
transmitter, more modern units have separate transmitters for each
dipole, or for a row of dipoles.

Ed> power, or is a separate transmitter antenna used? TIA

no, a separate antenna is not necessary, not at least for "normal" air
traffic control/air surveillance radars. Those huge OTH monsters are a
different beast of course... The separate thing you see on most radars
is the IFF antenna, recognizable because it is turned a few degrees
ahead of the main beam.

You mean on something like this?

http://www.raytheon.com/capabilities/rtnwcm/groups/ncs/documents/content/rtn_ncs_products_tpq37_pdf.pdf

It would depend on the design, but in general, yes, the flat plate does
both.

No a washed ham would be one who showers or bathes on a fairly
regular basis, and most likely uses some type of deodorant.
I suppose a car wash could be a suitable substitution. Or a lake.
It's not really that critical as long as water is involved.

> state of equilibrium per classical physics

If a full wave radiator IS in a state of equilibrium, whatever that
means,
why are you interested in fractional antennas?
If a full wave is so special, why is a half wave generally just as an
efficient a radiator as a full wave?
Something for you to ponder during your next visit to the
water closet.

And likewise I'm sure. I'm going to go play in the dirt for a while.

And just how would you be able to measure the SWR on the inside of the antenna element?? But I guess that you might assume that what ever the SWR on the line, and therefore you would take 1/2 for the outside of the element and the other half for the inside of the element... but wouldn't that cancel each other, and if it did then wouldn't the SWR drop to zero?? I am really confused!

Believe as you personally wish, Art.

But note that your belief is not supported either by theo-
retical or practical physics, or decades of field experience.

Instead of challenging the readers of your posts to prove
that you are wrong, you might take the time to research and
show SCIENTIFICALLY that you are right (if you can do so).

Mike, it is not about ignorance or how we were tested. We all start from a base of no knowledge. The test doesn't make a ham, it is the enquiring interest that makes us hams.

We are promoting ham radio to a different population, one that is more excited by the box with lights and knobs, than an enquiring interest and understanding of how it works.

Then add the economic factors that it is cheaper to buy an antenna complete than to buy the ladder line it contains... and people have a economic rationale for passing up the opportunity to do, to discover, to learn.

The getting of knowledge often has monetary cost... the question individuals need to ask is are they worth the investment in themselves.

The point about *our* new (VK) hams is that with just six hours investment in the hobby, they aren't well equipped to see through outragous claims of some antenna manufacturers. My perception is that there are many more US sourced wire antennas of the magic kind appearing on the bands here in VK since the introduction of our Foundation Licence.

Hello Scot,

Now it becomes a different story. You are talking about large relative BW. The concept of radiation resistance is nice for small structures, but in case of large structures (for example traveling wave antennas), you get (for example) impedance transformation.

A flaring and widening parallel strip transmission line has almost constant real input impedance for frequencies above the quarter wave length, without any resistive damping. However when the design is not OK, the radiation pattern can be frequency dependent and may show notches in the desired direction for certain frequency ranges. Also the radiation centre may vary with frequency.

Some wide band antennas create a nice impulse response by absorbing most of the power in resistance (resistive loaded dipole). Others are backed by wide band absorbing material, to avoid frequency selective reflection.

So one can make an antenna with close to 50 Ohms real impedance over wide frequency range (so no oscillatory behavior), but it does not mean that such an antenna is good for your application as you also have to consider radiation pattern (versus frequency).

Best regards,

Wim

Synthetic Aperture Radar (SAR) isn't usually the rotating antenna thing. SAR would be on some sort of moving platform (a plane or satellite, for instance, although SARs have been done on cars and boats and balloons)

Perhaps what you're thinking about is a phased array antenna? The flat plate thing is the antenna, and might be either totally passive (and can work for both transmit and receive) or active, with lots of T/R modules.

What about folded dipole vs non folded dipole? Rrad is the same, but
Zfeed is different, even in the lossless case. Or any antenna where
there's some built in impedance transformer (stubs, lumped components,
etc.)

As others have mentioned, that's not synthetic aperture radar. See
the article at:
<http://en.wikipedia.org/wiki/Synthetic_aperture_radar>
for explanations and references. Note that either the target or the
radar has to be moving for SAR to work. A mess of small transmitters,
scattered over a wide area, will also work. A rotating radar antenna
(phased array, bedspring, or dish) will not work.

One example is the SRTM (Shuttle Radar Topography Mission), which used
interferometry and a synthetic aperture radar to map the planet. In
this case, the shuttle was moving and the ground was relatively
motionless.
<http://fas.org/irp/program/collect/ifsar.htm>
<http://www2.jpl.nasa.gov/srtm/>
Since there was only one space shuttle in orbit, the antenna must both
xmit and receive.

David
When viewing the antenna from an equilibrium point of view which is a
staple requirement of all electrical laws
one must assume that all forces/vectors equal zero (Newton)
Following this dictum physics state that foe equilibrium the charge on
the surface of a radiator does not move
linearlly there fore, there cannot be a linear force or vector to
oppose it. From this it is stated that there is no movement
in linear form else where which includes the center of the conductor/
radiator when the radfiator is one wavelength or multiple there of.
Now we have the case of a fractional wavelength radiator. In this case
one is aware that charges do move in a linear
direction as evidenced by "end effect". Therefore by following the
standard laws of physics there must be a
balancing force/vector in the opposite direction and the only place
that vector could be is in the center of the conductor
One should also be aware that a electrical curcuit for a fractional
wavelength is a series circuit and a parallelel circuit for a
fulle wavelength both of which are closed cuircuits when determining
current flow of a radiator so one can itemise the electrical circuit
in detail with respect to the components on the actual radiator to
ensure compatability.
Now according to my theory of radiation the forward current on a
radiator is opposed by closed circuit eddy current
which in combination provide a angular rotational force on any
residing particle which allows for directional levitation or
projection.
When the current of the radiator reaches the end of the radiator it
closes the circuit by entering the center of the conductor
(assuming the arrangement is not in a state of vacuum)under circular

surface current cuircuit where it is still in existance.
The internal current flow is solely resistive in nature comprising of
theseries resistance of the material used and not radiative.
Now David, if you can point to a description that differs to the above
and follows the laws of physics I would be happy to look it up and
study it , but in the final analysis one must be able to determine
the state of the conductor at it's center at all times.
David, my explanation is based on the world of physics as I know it.
It is not based on opinions from those who never graduated from high
school or those who have not studied physics and rely solely on the
written world or heresay. Hopefully any responses will be likewise.
Have a happy winter discussing physics and its application to antennas
and radiation which is what this newsgroup initially was generated for

Elementary my dear Watson as one Englishman said
Best regards
Art

I believe that the Aegis warship radar is a phased-array system, akin to the PAVE PAWS radars that have been in the ham press lately due to QRM issues on both the east and west coasts of the US (some ham 440 repeater systems have been required to mitigate interference to PAVE PAWS and some have gone off the air as a result).

Mabye. Most recently, the term comes from cold war era references to
the GUM (great unwashed masses). This was a derrogatory term for the
average intelligence of the general public. The origin of the term
dates back to merry olde England, where it was used to refer to the
lower classes:
<http://answers.google.com/answers/threadview?id=29346>
This may be appropriate for ham radio if you have an elitist view of
the Extra-Class license, accompanied by the usual snobbery. As your
FCC ULS page shows you have an Advanced class license:
<http://wireless2.fcc.gov/UlsApp/UlsSearch/license.jsp?licKey=410939>
this is entirely possible, but improbable. To avoid confusion, I
suggest you upgrade to Extra-Class so that your self image improves,
and so that you not consider yourself being viewd as a lower class
"unwashed" ham.

We have a substantial number of hams locally that are only interested
in emergency services and have no interest in the technical aspects of
ham radio beyond operating their radios. I'm sure they will be
thrilled to know that their views are of no consequence.

Yea verily. Methinks trial by combat be the manner in which all
arguments should be settled. It worked well in the middle ages where

all the combative types conveniently exterminated each other, leaving only the peaceful and tolerant, thus laying the path for the Renaissance. Perhaps it be a worthy enterprise to return to trial by combat in ham radio. That should clear out the endless political debates, reduce pileups, and promote harmony on various bands.

Art, once upon a time, a long time ago, I first heard the word, or concept, called "skin effect". It seems that somehow, current at RF tends to stay near the surface of the conductor, going less deep into the conductor as frequency rises. In fact, at frequencies we 'unwashed' hams use routinely, the current hardly penetrates the conductor at all. Consequently, if the conductor is the radiating element of an antenna, and it is a solid, there is no way the current can enter the center of the conductor and travel through the mass of the conductor.

I also heard a long time ago the word "reflection." Seems that many savants discovered that when the current reaches the end of the radiator (conductor) it sees an open circuit, which the savants say causes the current to reverse its direction and flow back along the "surface" of the conductor. I also seem to recall some of those savants say that the combination of the forward current and the reflected current esstablishes what they call a 'standing wave.' Art, are you at all familiar with what I'm saying here? These savants have been able to prove that a standing wave exists on the radiator by moving a fluorescent bulb along the radiator for all to see.

So what I'm asking you to explain, Art, is how could this proven standing wave exist on the radiator if the current reaching end of the radiator now goes into the center of the radiator to propagate only through the mass of the conductor, and seeing only the resistance of the conductor?

You've told us this happens, Art, but you haven't explained why. Now Art, please explain this concept to all of us unwashed hams.

Walt, W2DU

No, I don't go along with those who choose ethnic cleansing
nor by those who accumulate the most wealth or those who determine
that God is on their side or the strong that are determined to
dominate
the weak. All nations that have followed this path in history lose out
in numbers
until their ways change, never to rise again as the future holds for
them " kill and be killed" by the many they have harmed.
I suspect that the next change in size of nations
will be the Middle East as all sides have moved towards permanent sin
that will never be forgiven and where some are willing to give
themselves
while taking all, leaving nothing but a desert while the tolerant have
presettled
else where they remove themselves from pre ethnic pasts.
Could we now possibly go back to radio and antennas which is what the
newsgroup
is set up for?
Art

> there's some built in impedance transformer (stubs, lumped components,
> etc.)

This question comes up from time to time. The answer is that radiation resistance is the resistive part of the antenna impedance when all losses are zero, and this resistance can be defined at (or "referred to") any point on the antenna, including the feed point. Some text authors use a more strict definition, for example, the resistance referred to a current maximum. But this isn't at all universal, and many such as Kraus adopt the more general definition.

This allows us to call the feedpoint resistance of a lossless folded dipole the "radiation resistance", a practice that's gotten quite a few people into trouble when using the well known formula for efficiency

Eff = Rr / (Rr + Rl)

where Rr and Rl are the radiation and loss resistances respectively. The fact is that this equation is just fine for folded dipoles (or monopoles, where it more often causes trouble), but you have to refer the loss resistance to the same point as the radiation resistance. (In the case of a folded antenna, this means transforming it by the same factor.) In a folded monopole where Rl is primarily ground system resistance, you have to multiply the ground system resistance by 4 to get Rl referred to the feedpoint. Then you can use the lossless feedpoint resistance for Rr. Or, if you choose, you can use the untransformed impedances, in which case you use ground system resistance directly for Rl but divide the lossless feedpoint resistance by four for Rr. Either method is equally valid and both give the same result, as they should. But you have to be careful to specify the point to which Rr is referred, so Rl can be referred to that same point.

A common mistake (made repeatedly by many people, some very well known) is to use the lossless feedpoint resistance for Rr but the untransformed ground resistance for Rl. This leads them to the incorrect conclusion that "folding" a monopole improves the efficiency.

I don't know why you say somehow. Only the surface of a radiator
radiates and the opposing force to the time varying current
known as eddy current changes its depth of penetration with frequency

In fact, at frequencies we 'unwashed' hams use routinely, the current
> hardly penetrates the conductor at all.
Again quit true

Consequently, if the conductor is the
> radiating element of an antenna, and it is a solid, there is no way the current

The only thing stopping the fliow of current is the eddy current. The
eddy current
is not present when current flows thru the center of a conductor, nor
is there
radiation from the center of the conductor and the copper resistance
of the center
is certainly less than the provided current and skin resistance that
would occur
if the currfent behaved like salmon and fought it's way back
upstream.

>
> I also heard a long time ago the word "reflection." Seems that many savants
> discovered that when the current reaches the end of the radiator (conductor) it

You are moving away from the subject at hand by not declaring what the
radiator is !
For instance there is no evidence that the provided current reverses
itself on a full
wave quad preferring instead to close the current circuit by returning
to the sourcewhich is what standard
physics teaches. There are two radiation circuits, a series and a
parallel circuit
both of which are continuous and closed circuits.

which the savants say causes the current to reverse its
> direction and flow back along the "surface" of the conductor.
Ther may well be current disturbance on the outside of a radiator but
the
main current path is always the one of least resistance to complete a
closed circuit.

I also seem to
> recall some of those savants say that the combination of the forward current and
> the reflected current esstablishes what they call a 'standing wave.'
Well I recognise that there can be disturbances but none that are
powerfull enough to overpower the
main current applied to the radiator.

Art, are
> you at all familiar with what I'm saying here?
Yes. You are trying to apply a foundation for a book

These savants have been able to
> prove that a standing wave exists on the radiator by moving a fluorescent bulb
> along the radiator for all to see.
I have never stated that a standing wave does not exist

First of all the standing wave is a disturbance along the path of
current flow
but not so strong as it can overpower it's provider., physics would
never support such a notion.
I previously stated that radiation can only occur from the surface of
the radiator
since it is the eddy or Foucault current that can provide levitation
to resting particles. When current flows thru
a material center it only encounters copper losses as there is no eddy
current generated.

>
> You've told us this happens, Art, but you haven't explained why. Now Art, please
> explain this concept to all of us unwashed hams.

I have stated many times what is happening. I reject all notions that
the applied time varying current can be overcome
from its pursuit of returning to its source as it will always follow
the path of least resistance and wil, never generate
a negative force that destroys equilibrium or suggests that energy can
be create.

Frankly, your concentration on reflections with respect to radiation
is just a way to promote a book while at the same time
ignoring what provides communication which is the main issue with

respect to antennas. When you get down to the real
issue of what creats radiation you will find it much easier to
explain reflections instead of just trying to substantiate
possible answers to the frequent abnormalities of your position. I
challenge you to show that when the arbritary field enclosing a static
field
accompanied by the addition of a time varying field applied to said
enclosed field in equilibrium does not equal Maxwells laws.
If it does then the action of particles is a given with respect to
radiation and thus destroys your notions with respect to reflection.
Provide a service to ham radio, Show that the said addition to
gaussian law does NOT equate to Maxwells findings and thus the
present teachings are correct and my theorem is not.

>that God is on their side or the strong that are determined to
>dominate the weak.

Well, those are usually the winners. If you don't "go along" with
them, it's highly likely that you will be among the losers. That's an
acceptable proposition in a country that protects, supports, and
sometimes even subsidizes the losers (i.e. government bailout). You
might find it more comfortable to be among the winners.

>All nations that have followed this path in history lose out

All nations? Well, Jews have maintained their cultural and
nationalistic integrity probably the longest. We also do quite well
in collecting wealth. We're not into ethnic cleansing, although there
are factions that wouldn't mind doing that to the neighboring Arab
states. Lots of other examples (Persia, China, American Indian
nations, Egypt, India) that have been around for a long time. They
all have their ups and downs, but all seem to survive.

For a nominal charge, I'll supply the needed forgiveness. As for
leaving the middle east a deserts, it has always been a desert. Not
much changes above ground level.

Possibly yes. However, ending a sentence in a preposition is a
violation of proper grammar, up with which I will not put.

Hi Art
Trying to build a picture here.
Let's say I have a 1/2 wave dipole, and I drive it such that one ampere
is flowing at the feedpoint. Let's agree to use amps RMS and volts RMS
at 14 MHz

for this example, just for clarity.
If I measure the current a short distance from the feedpoint, it's a bit
less than one amp. Correct so far?

If I tease the antenna conductor apart and measure the current flowing
on the
outside with one RF Ammeter, and the current flowing in the
center with a second ammeter, what are the two currents?

Thanks!

Source record: 20585

I'm trying to build a decent performing 2M coaxial skirted antenna and have a question about its design for maximum efficiency.

I based the "hub" on an SO-239 connector. I soldered my RG8X cable center conductor to the solder pin center conductor and brought the shield braid out in two places.

I cut a 19" piece of half inch copper pipe, cut 4 half inch slots on one end, fanned the slotted end out slightly to fit nicely against the SO-239, and slid this pipe over my coax and up to the SO-239. I brought the two braid lengths previously prepared out through two of the rather fat slots, soldered the pipe to the SO-239 and the braids were soldered to the pipe where they came protruded out the slots.

I soldered an 18 1/2" brass welding rod to a PL-259 center conductor and screwed that the the SO-239 for my radiator. The copper pipe assy and coax slide nicely down into a length of 3/4" PVC . This makes a very nice break-down package for transportation and portable work.

Back to my question: I am measuring about 125 watts forward and 4-5 watts reflected at my desired frequency (146.000). While this may be acceptable to some, I would like to get the match down to 1:1 SWR.

Are there any design deficiencies in my proto-type? Can anyone suggest something I might try to improve the match? Is there a "rule of thumb" regarding the construction of such antennas?... length of coaxial skirt vs. antenna element?

I appreciate any feedback on this. Thanks.

I suppose I could provide a picture if anyone requires it....

remember, too low an swr can kill you!

To get exactly 50 ohms you may need a fatter copper pipe, or some other
change to the geometry. if ti works well as it is i would leave it alone.

125 watts forward with 5 watts back is a VSWR = 1.5:1

The characteristic impedance of a coaxial antenna is about 75 ohms.
The best you can do with your present arrangement is therefore about
1.5:1 which is what you're getting.

To do any better, you'll need some way to match the 75 ohm antenna to
your 50 ohm system. That's usually an odd multiple of 1/4 wave coax
section, with an impedance of 61 ohms. Something like:
<http://www.repeater-builder.com/rbtip/matchingstubs.html>

> I suppose I could provide a picture if anyone requires it....

A JPG is worth 1000 guesses.

Also, you might want to do your testing with something less than 125
watts, as accidents and miscalculations might become expensive.

Sorry. I have enough problems trying to explain my own theorem which
follows Newton,
Gauss and also Einsteins dream in identifying all four universal
forces which provide the key
to the explanation to radiation and discards the notion of traveling
waves in the atmosphere.
Until this group has the courage in disputing that the addition of
radiators and a time varying
current to a Gaussian arbitrary static field in equilibrium is
mathematically identical with Maxwell's laws
AND also accept the Grand Unification Theory which I have supplied the
proof of authenticity change will never be accepted regardless of
first
principles that they learned in their only period of learning where
they apparently were placed
in a position of understanding all the laws of the Universe and every
thing else. If any of those
that are educated enough to take up the challenge from first
principles then they are in danger of being mocked
by those who cannot accept change,Thus it is safer to abide by books
that are full of just conjecture with respect to radiation.
There is nobody in this newsgroup who is willing to take the challenge
and be subject to the ire of the many talking heads.
The comparison of my extended Gaussian law of statics to the laws of
Maxwell will never be attempted by a ham whether
on this newsgroup or else where. On top of thatm, the theorem will
never be attempted or accepted when applied to NEC or mininec programs
with optimizer regardles of the fact that computer programs are
founded on the laws of Maxwell which includes the four forces of the
Universe plus the foundation of equilibrium NONE of which are included
or accounted for in the design of Yagi's or other planar devices.
To be frank,, most of this group have asked for a definition of the
term equilibrium, this despite the fact that there is no law of

physics in this universe that does not expect the condition of
equilibrium as a a given for the validity of any law with respect to
our universe. This is in addition to all suppliers of technical
information to Maxwell to condense into a smaller number, all
specifically stated that the information given were valid ONLY under
the conditions of equilibrium
As far as your question goes, you cannot create energy so the energy
supplied is the same that returns to the source
neglecting losses in the closed system i.e Energy supplied to the
"system" cannot be overcome by the disturbances created by the initial
energy
Best regards
Art Unwin KB9MZ.....xg
which has never been extended

Johnny's dad wanted to read him a story from a book, but Johnny wasn't interested. So his mean father sent him to his room without supper. After supper, his father went to Johnny's room to try again. And Johnny said,

"Why did you bring the book that before dinner I didn't want to be read to out of up for after?"

That was the record of six prepositions at the end of a sentence submitted by readers to "Charlie Rice's Punchbowl" in Parade Magazine oh, I dunno, 45 years or so ago. I guess remembering stuff like that is why I don't have room to remember where I parked the car or left my glasses.

Actually, this is acceptable to just about everyone. And those for whom it's not don't usually have a rational reason for it.

Here are some ways to do it:

1. Lower the impedance at resonance by making the top of the antenna into an inverted cone shape, by using fanned out multiple conductors. You'll have to adjust the length of the conductors and possibly the sleeve to maintain the same resonant frequency.
2. Build and use a simple matching network, preferably placed as close to the antenna as possible. Then you can adjust it for a perfect match.
3. Use some other form of impedance transformation such as a stub matching network or transmission line transformer.

If you do things right, it'll work the same when you finish as it did when you start. But you'll feel better seeing zero "reflected" power on your meter, and the placebo effect is not to be sneezed at.

Source record: 20592

Ed,

You might have expected the feedpoint impedance to be around 70 ohms. It will depend on the feedline configuration, because you haven't taken much is the way of measures to decouple the feedline.

Your measured fwd and ref indicates VSWR~=1.5 which is consistent with 70 ohms, but you haven't measured 70 ohms.

Assuming though that such an antenna should be close to 70+j0 at resonance...

If you did want to incorporate an impedance matching system that doesn't compromise the portability you have described, you could try a twelfth wave transformer with 29.3° of 50 ohm coax from the feedpoint, then 29.3° of 75 ohm coax then any length of 50 ohm coax to the transmitter.

For example, for 146MHz, that could be 137mm of Belden 9258 (RG8/X) then 139mm of Belden 1189A (RG6/U) then any length of 50 ohm coax to the tx.

Owen

Dave, Jeff, Roy, ...

Thank you for the excellent responses to my questions. I am considering any and all of them.

One note: I erred on my previously stated power levels.... it was 1.25 Watts forward and about .05 watts reflected. Same ratio, but less energy.

Ed

I sense a little confusion about the differences between time and frequency domain analysis. This is really common.

Impedance is a frequency domain concept, and works in the time domain only in a very limited way. Impedance consists of two parts, a magnitude and phase or a resistance and reactance. Reactance is a function of frequency, so it has no simple equivalent meaning in the time domain which encompasses a very wide range of frequencies all at once. Likewise for magnitude and phase. So only resistance is really useful in time domain analysis. Some impedances, like a low loss transmission line's Z0, are essentially purely resistive, so they're useful. But complex impedances, in general, are not.

With a TDR system you can readily see and interpret frequency-dependent resistances like skin effect, "capacitive" and "inductive" regions (where the Z0 of the transmission path is lower or higher than the reference respectively), and a lot of other features. But it's difficult to get an intuitive feel for the relationship between a TDR and frequency domain analysis of a lot of circuits which change characteristics rapidly with frequency (in other words, which have a reasonably high Q).

A TDR generally produces a fast rising step or its derivative, a narrow pulse. Viewed in the frequency domain, this step or pulse has energy over a very wide range of frequencies, but very little in any narrow range of frequencies. So if a circuit has high Q, there's usually not enough energy at or near the resonant frequency to get the circuit to ring at any appreciable amplitude, and you often won't even see the circuit with a TDR. (By this I mean that, for example, a high Q series resonant circuit looks like an open and a parallel resonant circuit like a short, which are essentially their impedances except near resonance.) A dipole is a pretty low Q circuit in the frequency domain, so you can see a periodic time domain response that corresponds to its basic resonance. It looks like a lossy, open circuited transmission line whose characteristic impedance increases from the feed point outward. The response, which I'm sure you can also find somewhere on the web, looks something like a distorted (due to the changing Z0) square wave whose amplitude diminishes with time (due to the radiative "loss").

Hi Ed

If you are in search of precission, I'd suggest that you consider using 70 ohm coax to feed the 70 ohm antenna. There are some very good 70 ohm coax available at low cost. Their loss will be a fraction of a dB less than your RG-8X. Their OD may be smaller (that helps a little to decouple the stub from the coax). TheVSWR on the 70 ohm line will be lower than on the 50 ohm line. You will then be able to construct a tuning network at the

junction from the transmitter to the 70 ohm line. There will be essentially no meaureable VSWR anywhere in the system.

I didn't do the math, I punched the numbers into TLLC
(http://www.vk1od.net/tl/tllc.php).

Of course, the reason I was so specific is that translation from the
29.3° depends on the velocity factor... so use the velocity factor for
the cables you have at hand. (For example, if you use RG59, it has a
very different velocity factor to te 1189A, and you need to adjust
accordingly.)

There is a little on the twelfth wave transformer, including a graph of the lengths for different transformation ratios at http://www.vk1od.net/RG6/index.htm .

Have fun.

If you read the article, you might try evaluating the systemusing TLLC with
say 10m of feedline configured with:
- the twelfth wave transformer near the antenna and 10m of RG8/X, and
- the twelfth wave transformer near the tx and 10m of RG6.

Intesting, the cheapest option (mostly RG6) is the one with the least loss!

Walt,

I had not heard of these Adcock antennas and am interested on the time of their deployment to Europe. By chance, do you know when that happened?

My uncle was Robert LaMotte, radio operator of the ill-fated B-24 bomber "Lady Be Good" that was lost in a bombing run over Italy in 1943 and believed to have ditched in the Med. The ship and crew were found 16 years later in the Libyan desert, victims of a "read from the back of the loop" tragedy. They abandoned ship when running out of fuel, believing they were over water but had overflown their airstrip and in fact were over the desert. (Google "lady be good" for lots of links)

The family has always followed any news about these types of mishaps, and I am curious to know how soon after my uncle's loss any technology might have appeared to prevent the accident.

Thanks in advance for your response,

-larry

which laws specifically require equilibrium? any law that talks about
energy transfer, which is most of them, require non-equilibrium. energy can
not flow where everything is in equilibrium, by definition! oh, but wait,
you have not supplied that definition yet, so you must have a different
definition in which energy can flow despite equilibrium... lets hear it art,
that is worthy of a Nobel prize for sure!

>This is in addition to all suppliers of technical
>information to Maxwell to condense into a smaller number, all
>specifically stated that the information given were valid ONLY under

Give quotes. i want to see in the original writings where Gauss, Ampere,
Coulomb, Ohm, Lorentz, etc all require some kind of equilibrium. Come on
art, you claim to be above all of us who have studied such things for years,
and yet you can not define even your most basic condition that you keep
ranting about.

So your homework assignment is to in one equation do this: Define
Equilibrium.

The meter indication will be essentially zero only if the directivity of the device measuring reflected energy is extremely good (as in 60+ dB).

The leakage of forward energy into the reflected sample that is present in typical commercial products will lead to (mis)adjusting the load Z to whatever produces zero on the reflected meter. However some amount of reflected energy will be needed to cancel the leakage of the reflected coupler, in order to obtain that "zero" reading.

And then the reverse energy is not really zero, and the true load SWR is not really 1:1.

Hi Owen

Another way of avoiding the math is to use both a Smith Chart and an
overlay of a Z Theta Chart. The problem of choosing line lengths and their
Zo them becomes intuitive. But any "perfect match" does depend heavily on
knowing impedance rather than VSWR, as you know.
The load impedance ploted on the Smith Chart can be assummed to translate
to any impedance on the circle of constant VSWR for any load impedance.
The impedance moves along the line of constant "Theta" on the Z Theta Chart
for a change of Chart Z.
With the overlay of the two charts, it is fairly easy to see what lengths
and Zo will produce the best match.

David,
I am so glad that you keep writing. No I can't spend a lot of time
responding
because of the postings content. What I do find important is that
everybody
exercise to right of free speech as it allows all to determine who
and what you really are

Most people would look at a dictionary for themselves to determine what the word
equilibrium actually means as well as the recordings of history where all the masters of the past
has made a stipulation about the conditi9on of equilibrium as a staple of the validity of the laws that they espoused.
You should also know that Einstein was convinced that radiation held the clues as to the nature of the four forces of the universe
He never stumbled on the answer but he never ditched the idea of equilibrium as a staple
for the laws of relativity. Nor have other discarded same in string theory or the burgeoning science of particles
in our universe. I am betting that there are some knoweledgable people out there that do read your postings and place you in a certain category.
I would also point out that those who try to distort the ideas of reflection are the owners of the largest threads on this newsgroup where there are many that exceed a thousand posting where many are unable to turn the espoused ideas of reflections into a closed circuit of understanding since it involves so many positions that are unsustainable to those familiar with the state of the art.
All one has to do to destroy my theory and the new clues that emanate is to add radiators and a time varying current to that enclosed within a arbitrary border is in a state of equilibrium as per Gauss to determine the difference in the math to that espoused by Maxwell to detroy my position. All one has to do is to use any computor program on antennas with an optimizer, insert any dimensions that do not guide the computer in the direction of a planar design ie. all dimensions being non repeatable and then determine why the programs based on the laws of Maxwell consistently provide antennas that are in a state of equilibrium. No ham on this group have proved false my assertions with respect to radiation since their learning stopped at the point of leaving university where they still hold on to the books of yesteryear. On top of all this there is no evidence that there is any advantage in having rafiators in a straight line, or that size is a factor for any antenna WHERE there is accountability for ALLl the four forces that aid in the production of radiation.
So David keep writing as I have given you lots of data to refute so that posters can understand who and what you are .
Great day for antennas so get off the net and enjoy your self
Best regards
Art Unwin KB9MZ.....xg

The book idea sounds interesting. there seems to be a lot more
printing
outside theo academic world these days to counteract their iron hold
on science discussions.
The best independent book that I own is
The secret of gravity and other mysteries of the Universe by Weldon
Vlasak which I recommend to anybody
in the ham radio world. Let me know when your book gets on the Oprah
list of the book of the month
so I can see you on TV
At the moment I am putting a different rotatable antenna for top band
on my tower while the weather is still good
tho there are a lot of hitches that get in the way when at the top !.

Hi Richard

As you know, I have been far away from the antenna design community for
such a long time that I feel like a beginner today. So, I wouldnt have
considered anything i know to be "exotic".
For those who havent used the Z Theta Chart, it is identical to the Smith
Chart, but expressed in polar coordinates (Impedance magnitude with its
angle).
With both a Smith Chart and a Z Theta Chart of equal radius and overlayed,

a pin hole thru both will identify any impedance with real Resistance. The value identified on the Smith Chart is given as R+/- jX.. The value identified on the Z Theta Chart is given as Z Angle Theta.

The use of both charts together is a great tool for impedance matching with transmission line sections. It is quick and simple yet it is quite accurate. An impedance, plotted on the Z Theta Chart moves along the lines of constant angle when the chart Impedance is changed. That lets the designer plot any impedance on the Z Theta Chart with, for instance 50 ohms as its center, then immediately see where the impedance will move if the Chart impedance is changed to the value of the new transmission line impedance chosen for the transformer, for instance 70 ohms.

Jerry

Hi Jerry,

Your solution is rather exotic for this group, but I have encountered
it in my Metrology days as part of the HP legacy. The method you
described is missing from this article, but it gives the group a
picture of the chart, none-the-less:

You could try putting 4 ground plane elements off the SO-239 connector, I'm told they are to help with standing wave problems. I've never used ground plane antennas, but it wouldn't take much effort and could be worth a try. I use the MFJ 269 antenna analyzer when building antennas and find that the unit saves lots of time. Of course, I am always open to "new proof" (heck, even old proof will do!)

However, in a capacitor, I do believe that power and/or current does travel the surface of the plate(s.) To make a jump from this acceptance, to one accepting the same occurs at rf, where a signal actually leaves the antenna and enters/"rides"/travels/propagates the ether, is easily made, at least by me.

Since, obviously, the signal MUST leave the surface, why not just travel it (shortest distance between two points--and all that) to begin with?

I do believe it does travel the surface, if at all possible; however, given a very thin radiator and/or a very large PA, it would not surprise me if you can't force the current/power/VA to another route ...

You could always construct one of the "fancy" and esoteric 50:75 ohm ununs to accomplish, however, you would probably not gain much if anything, as there will be some loss--even if you construct the unun from optimum material.

However, if ONLY the mismatch bothers you (and not the insignificant 4-5 watts) and not the actual loss of watts--it is an option. But any "gain" you would get from this option would be virtually "insignificant", or so in my humble opinion.

Hi Jerry,

The Z-Theta Chart has actually been around a long time, well known as the 'Carter' Chart, developed by Philip Carter, an early RCA transmission-line and antenna inventor, around the same time as Philip Smith developed the Smith Chart. In one of HP's Application Notes it is incorrectly called the 'Charter Chart'. But you are correct, overlaying those two charts is often very helpful.

But of course John it will travel along the plate
that is natures way of seeking the point of least resistance
to cross. Remember that the plate of a capacitor represents an
inductor which in combination with a capacitor has the same
constituents as a
tank circuit except that it is not being subject to a time varying
field.
I would like to say that I was in error stating that the when
programers made the computor program
on antennas on the premise of a contunuous sine wave they are quite
correct when viwing it from yhe stand point of a
tank circuit.

To make a jump from this
> acceptance, to one accepting the same occurs at rf, where a signal
> actually leaves the antenna and enters/"rides"/travels/propagates the
> ether, is easily made, at least by me.
I think the case is slightly different, it needs a continued varied
current to
achieve a stable eddy current which gives the ability for levitated
charge movement
and in the capacitor case the point of least resistance is pre
established after the first varient in current
and it is the current movement inconjunction with the eddy current
that provides the essential spin needed
for inline projection

>
> Since, obviously, the signal MUST leave the surface, why not just travel
> it (shortest distance between two points--and all that) to begin with?

Exactly . After the first pulse of current flow the point of least
resistance

is attained so yes the charge will travel at that specific point.
When a capacitor breaks down you cannot see the path taken by the
current
on the initiating plate but you can see a point trace where the charge
impinges
on the reeiving plate as opposed to the whole area of the plate.
Remember convention if correct states that a capacitor does not
radiate
>
> I do believe it does travel the surface, if at all possible; however,

I don't see how that could happen except when a charge is released it
produces a
lesser resistance route by ironizing of the medium travelled either in
the initial case
or of a resultant discharge travelling thu ozone.

Well, I AM one which can picture, theoretically, the antenna as a "transformer"; and, the antenna taking the signal from the feedline and "properly interfacing"/matching/transforming-its'-characteristics to the ether (actually, the ether looks like a "spherical turn" of superconductor which envelopes the antenna, as someone, either intentionally or unintentionally, mentioned in an earlier post in another thread ...)

But, as some gurus have pointed out, REAL PROOF for this is lacking ...

However, very ancient material incorporated the ether into theories of those times. Then, Einstein, in error, dismissed the ether totally--then he reneged and changed "luminous ether" to "gravitational ether." It would seem the "luminous ether" would be fine, if you only dealt with photons and/or "waves of photons." "Gravitational ether" would allow for much, much more ... in that one point is a LOT to contemplate ...

It seems to me, that most, past, authors/experimenters/scholars having been "fooled once" and changing from the ethers existence to its' non-existence, would NOT take a chance on being "fooled again"--they began to "ignore" the ether ...

End-point being, there are loads of equations and formulas laying about which craftily ignore the ether ... indeed, in my younger years it was not uncommon to find physicists totally ignorant of Einsteins acceptance of the gravitational ether (indeed, my own education was along these lines, only later readings on Einstein brought forth this error.) "They" would state that Einstein denied the ether, and one would have to go to great lengths to convince them different, if at all! ... go figure.

It is still quite common to find hams will have "NO ETHER!"

And, the point of all that? We shall, often, need to agree to disagree ...

Regards,
JS

What blows my mind John there is nobody willing to do the math with
respect to my extension of GAUSS
It blows my mind when a ham with a doctorate comes along and supplies
the mathematical proof and the math is denied
by the guru's on this newsgroup.
It blows my mind when hams state a conductor must be straight when
they use helicals in so many places yet despite the denials
they will not do the math for themselves but continue to ask me
endless questions so they can continue arguements.
Then they deny I have such an antenna and an Aussie who obviously
likes to bet offered a wager of what was it $1000 US ?
and nobody took him up on the wager. Then there are computor programs
that push aside Yagi antennas in favor of those
in equilibrium which support what I have found and these programs are
designed around Maxwell who is now arpparently losing favor with hams
tho professionals cling to it dearly. I have no problem with Guru's
disagreeing with me but I did expect a morsel or a small challenge
in at least one area other than look up the dictionary for them to get
the definition of equilibrium. And now we have a man who has written a
book
and preferes to tout this piece of trash rather than do the math with
respect to the radiation all on the basis that what he believes is in
a book that he wrote so it must be authentic. David take note when
your book comes out it may spawn a new science to rival classical
physics. It blows my mind that we have threads that break the thousand
mark on reflections or swr and then get repeated again and again
because of disagreements on the substance Now he is toting a later
edition hoping to collect some money from hams. Give me a break since
he will not do the math that I speak of probably because he can't
handle the difference in units between Gauss and Maxwell. You know
when OBAMA
wins the election on Tuesday hams will unite and declare McCAIN the
winner
John have a great evening
Best regards
Art Unwin KB9MZ.....xg

Gee it's too bad he didn't have a bunch of CATV hardline and a Motrac. All of this would be real simple.

I recall that there was a commercial AS "fire engine" antenna that never bothered with the matching at all because adding all the extra hardware for matching, wouldn't have justified the potential losses that might be introduced. Of course the main advantage of the antenna was that it could be elevated without need for reflecting plane or radials and thus wouldn't poke eyes out or get tangled. Otherwise a regular mobile mount or base radial kit would be advantageous.

Hi Ed, I think your SWR is about as good as you are going to get it.
What you have created is a center feed dipole with a feedpoint
impedance of about 70 ohms or so. One way to get a better match to 50
ohms is to flair out your coaxial skirt. Skirt at 90 degrees to the
radiator the impedance will be 36 ohms, 70 with the skirt at 180
degree. You will find 50 ohms somewhere in between, about 45 degrees I
think. This may be done at the expense of your radiation pattern. I
built something like what you are building a few years ago using sheet
metal rolled in a trumpet shape for the skirt. I think my SWR was

about 1.3:1. My metal mast and skirt connected together at the feedpoint. Whether or not the mast was insulated from the skirt of not didnt make any difference. If itis not clear what I am talking about think AEA isopole. While theirs was a 5/8ths we are talking about a 1/2 wl antenna.

Jimmie

Repeating someone else's advice in this way is a detached recommendation,
and if you don't understand it, a questionable recommendation.

Attaching radials as you suggest turns the antenna into a regular ground
plane antenna. One expects the feed point impedance at resonance to be
around 35 ohms, which would result in a VSWR of 1.5 when fed directly by
50 ohm coax. Much the same outcome as feeding the coaxial dipole with 50
ohm coax.

> I've never used ground plane antennas, but it wouldn't take much

Sloping the radials can raise the feedpoint impedance, but I think Ed
wanted an antenna without radials for his particular application.

Owen

Kreco Antennas in Cresco, PA makes a line of
coaxial dipole basestation antennas that exhibit
a 50-ohm feedpoint impedance. Here's the
website for their high-band basic model:

http://www.krecoantennas.com/hbcaxial.htm

They pull off this trick by, *I THINK*, shortening
the top element slightly and lengthening the skirt in
just the right way to achieve a match at a spot
frequency.

An interesting variant on the basic antenna is their
"shunt-fed" coaxial dipole that places the entire
antenna at DC ground for lightning protection. Here's
the webpage for it:

http://www.krecoantennas.com/shuntfed.htm

I've used their antennas in the past with excellent
results, but they are a bit pricey.

Yep. However, they recommended using 75 ohm coax cable. The loss of
equal lengths of similar size 75 ohm coax is less than 50 ohm. For
example:
RG-58c/u 0.20dB/meter at 150 Mhz (cheap 50 ohms coax)
LMR-240 0.09dB/meter at 150 Mhz (much better 50 ohm coax)
RG-6/u 0.07dB/meter at 150 Mhz (75 ohm CATV coax)

However, if you wanna run 50 ohm coax, the mismatch loss at the 75 ohm
antenna is about:
reflection_coef = (75-50)/(50+75)= 0.20
voltage = 1 - (0.2^2) = 0.96
20 * log(0.96) = 0.35 dB mismatch loss.
No big deal.

Hmmmm...
0.35 dB / 0.02dB/meter = 17.5 meters
At 17.5 meters, the losses of the 50 and 75 coax systems are
identical. Beyond 17.5 meters of coax, the 75 ohm coax delivers more
power.

I've been using RG-6/u for 2.4GHz wireless for quite a while. The
main incentive is that I can get the 75 ohm coax quite cheaply. For a
while, Hyperlink (http://www.hyperlinktech.com) had a rooftop 2.4Ghz
amplifier that was fed with 75 ohm coax. Alvarion/Breezecom also used
75 ohm coax in some of their BreezeAccess LB radios.

Someone eventually asks why 50 or 75 ohms. See:
<http://www.microwaves101.com/encyclopedia/why50ohms.cfm>

Motrac? Those are 30-40 years ancient. I used them for boat anchors.
Back then, I preferred GE radios:

The analysis you give assumes that the notional 'reflected power' is lost
from the system as heat. The old 'reflected power is dissipated as
increased heat in the PA' line.

In the real world, the power that a transmitter delivers to a non ideal
load is not so simply predicted, and it is entirely possible that it
delivers more power to the mismatched load.

Owen

Yes, I have done that, and they work very well. I found three radials sufficient, and if bent down about 45 degrees the match was perfect. However, for the application I am planning, the antenna must be very portable.... ground plane radials "stick out" but the coaxial skirted antenna has a very minimal foot print.... it can be packed in a very tight space.... just like any pipe.

Tnx.

That may well be; I am no expert on this; and, the point has missed my detailed investigation.

But, if memory serves me correct, when I fed a 50 ohm antenna with an old 75 ohm PA, equipped with plate voltage and current meters, I would have expected a dip (although it might appear slight) in voltage and a rise in plate current--indicating, that indeed, I was feeding "more power" to the load ... although not desirable ... extrapolating from this, feeding a 75 ohm antenna with a 50 ohm rig, I would expect the opposite.

Regards,
JS

I beg to differ somewhat. In order for the reflected power to
contribute to the incident power, the reflected power would first be
attenuated by the coax loss. It would then require a substantial
mismatch at the transmitter, which is unlikely. However, assuming
there is a mismatch at the source, some of the reflected power will be
sent back to the load (antenna), after getting attenuated by the coax
for a 2nd time. There may be some contribution, but it will very very
very very small.

Let's try some more or less real numbers. I kinda prefer doing
everything in dBm but hams have this thing about using watts...

Start with a 50 watt xmitter and 20 meters of LMR-240 coax at
0.09dB/meter for an attenuation of 1.8dB.

The power delivered to the antenna is:
50 watts / ((1.8/10)^10) = 50 / 1.5 = 33 watts
The 1.5:1 VSWR reflects 4% of 33 watts for 1.3 watts reflected.

The 1.3 watts is again attenuated by the 1.8dB coax loss resulting in:
1.3 watts / (1.8/10)^10) = 1.3 / 1.5 = 0.87 watts

Now, lets assume that the xmitter has a broadband output stage,
optimized for 50 ohms and lacks the ability to properly match 75 ohms.

Once again, 4% of the power if reflected, resulting in:
0.87 watts * 4% = 0.035 watts reflected

Once again, the power reflected from the source end (xmitter end) is
attenuated by the 1.8dB coax loss for:
0.035 watts / ((1.8/10^10) = 0.035 / 1.5 = 0.023 watts.

Therefore, you're correct. It's possible that some of the reflected
power adds to the incident power. However, it's a really small
amount. In this case, it's only 23 milliwatts added to 33 watts
delivered to the antenna.

Of course it doesn't matter, which unit system you use, but if you start
adding 'forward' and 'reflected' power in dBm because it is real
convenient, you have peformed a vector addition of power. Is that valid?

> 1.3 watts / (1.8/10)^10) = 1.3 / 1.5 = 0.87 watts

You start with a limited view of the mismatch, VSWR conveys only one
dimension of a two dimensional mismatch.

Your treatment of the forward wave and reflected waves as independently
attenuated is an approximation that will lead to significant errors in
some cases.

For example, what percentage of the power at the source end of the line is lost as heat in 1m of LMR400 at 1MHz with a) a 5+j0 ohm load, and b) a 500+j0 ohm load. The VSWR is approximatly the same in both cases but the answers are very different, one is almost 100 times the other.

Doesn't it stand to reason that as the length of the transmission line approaches zero, that the power lost transmission in this type of line in the high voltage low current load scenario is lower than the low voltage high current load scenario.

Another issue is that the V/I characteristics of a transmitter output stage is not necessarily (or usually for most ham transmitters) a straight line, in other words it does not exibit a constant Thevenin equivalent source impedance with varying loads and the application of some linear circuit analysis techniques to the output stage are inappropriate.

Nope. No need to complexicate things. I can safely assume a real 75
ohm load. I can cheat a bit and assume some multiple of 1/2 wave coax
cables, thus eliminating any imaginary contributions from the coax.

Please note that my purpose was to demonstrate that 75 ohm antennas
and 75 ohm coax will work adequately in a 50 ohm system. I think I've
done most of that. Including complex impedances to the calculations
will yield a more accurate result, but the resultant reflected power
that will be added to the forward delivered power, will be LESS than
the results produced by my calculations using only the real part of
the impedances.

It's only valid for the level of accuracy with which you are working.
For convenience, perhaps we can just assume that the re-reflected

contribution to the forward power is in phase, thus yielding the maximum delivered power. Any phase shifts between the two signals will result in LESS delivered power than the in phase simplistic calculation. I'm sure the accuracy might be useful for academic purposes, but my example demonstrated that only 35 mw was added to 33 watts, an error of 0.1%. Of course, that's ridiculous because the initial measurement of the originating 50 watts is probably only accurate to 2 significant figures.

Sure. It's good enough for a back of the envelope estimate of how much power the re-reflected signal can possibly add to the forward power.

>Your treatment of the forward wave and reflected waves as independently
>attenuated is an approximation that will lead to significant errors in
>some cases.

True. However, as long as I assume a 1.8dB coax cable loss, the reflected and re-reflected powers will be sufficiently low to be considered negligible. Including the necessary vector arithmetic to include the possibility of random coax cable lengths will improve accuracy, but not affect the result very much.

>For example, what percentage of the power at the source end of the line

I'll work out the exact numbers tomorrow, but I see your point. However, please note that I made an effort to use a REALISTIC example of a typical 2m radio, coax, and coaxial antenna arrangement. Of course, you can conjure a set of numbers that will result in a substantially increased calculation error. I can do the same thing if I take my example and simply reduce the coax cable length to the point where coax attenuation is dramatically smaller. A 100:1 load impedance change is not the same as a 1.5:1 impedance change (from 50 to 75 ohms)

>Doesn't it stand to reason that as the length of the transmission line

Ummmm... you lost me there. I've got a headache tonite. I'll see it
makes more sense tomorrow morning.

I really don't know if that's true for a 2m FM transmitter. I'm not
sure it even matters. The V/I characteristic (slope) is just the
source impedance of the output stage. Whether it's 50 or 75 ohms is
close enough for my simplistic calculation to be accurate without
throwing in non-linearities. The source impedance may be different
for a 50 watt radio, running at 1 watt, but not enough to make a big
difference. If the source impedance were magically 10 times as high,
the 35 milliwatts of re-reflected RF would become 350 mw and still be
a fairly negligible contribution to the delivered 33 watts.

Jeff, your re-reflection concept is complicating things.

Just consider a typical ham FM voice transmitter after steady state has been substantially established.

If the load was for example 70+j0 and the transmitter was connected by 2 wavelengths of Belden 9258, accounting for line loss we would expect the transmitter to see a load of about 68+j0 (VSWR(50)=1.4), ie the ratio of v/i at the output terminals of the transmitter would be about 68+j0.

Consider also the case where the transmitter was connected by 2.25 wavelengths of Belden 9258, accounting for line loss we would expect the transmitter to see a load of about 37+j0 (VSWR(50)=1.4), ie the ratio of v/i at the output terminals of the transmitter would be about 37+j0.

If you were to measure the output power of a range of such transmitters, it is unlikely that they will produce substantially identical power output under both conditions though the VSWR is similar, that the power is changed from that with a 50+j0 load by the same amount in all cases, or that the change is reliably predicted by your analysis technique (based on VSWR).

Your treatment of the 'forward power' as a constant with different loads, and the approximation of transmisssion line behaviour contribute error.

Additionally, the formulae you use do not account for non linear behaviour of typical output stages, gain variation at different output level, whether they reach voltage or current saturation with a given load, the effects of PA protection schemes that might limit current, 'relected power', 'power output' etc.

I would agree that a 70 ohm antenna at the end of 4m or so of RG8/X will *probably* not result in a large loss of output power, but I wouldn't agree with your results or method because it is not sound. Nevertheless, I understand why Ed might want to transform the load to 50 ohms, and he shouldn't be discouraged by flawed estimates.

Owen

PS:
You might dismiss my example of the 5 and 500 ohm loads on a short line as unrealistic, but it exposes a common misunderstanding that the loss per unit length when VSWR>1 is uniform along the line. If you want to explore the idea further, I have written some notes at http://www.vk1od.net/VSWR/displacement.htm .

Reflection of a single reflected wave is not the only mechanism
that can redistribute energy back toward the load. Superposition
of two waves at the source impedance (or at an impedance
discontinuity in a feedline) accompanied by destructive
interference can accomplish a similar feat. Non-reflective glass
is a 1/4WL matching section of thin-film that accomplishes the
same thing as a Z0-match.

To the best of my knowledge, nobody is taking wave cancellation
at the source impedance into account although it may be the
major source of the redistribution of reflected energy back
toward the antenna. It's explained on the following web pages:

http://www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and
the thickness of the film are such that a phase difference
exists between reflections of p, then *reflected wavefronts*
interfere destructively, and overall reflected intensity is
a minimum. If the two reflections are of equal amplitude,
then this amplitude (and hence intensity) minimum will be
zero." (Referring to 1/4 wavelength thin films.)

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity
will appear as *enhanced intensity in the transmitted beam*.
The sum of the reflected and transmitted beam intensities is
always equal to the incident intensity. This important fact
has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated, ... All of the photon energy present in

these waves must somehow be recovered or *redistributed* in a new
direction, according to the law of energy conservation ... Instead,
upon meeting, the photons are *redistributed* to regions that permit
constructive interference, so the effect should be considered as
a *redistribution* of light waves and photon energy rather than
the spontaneous construction or destruction of light."

Why does almost everyone seem to consider reflection the only way
to redistribute reflected energy back toward the antenna?

The correct method of adding power comes to us from the
field of optics in the form of the irradiance equation.
If we multiply irradiance by the cross-sectional area of
coax, we get power.

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(A)

where 'A' is the angle between the electric fields
of the two phasors.

Drill the holes out larger. You can use a mild acid like in Aluminum jelly
but the corrosion gets into the metal and makes it extremely brittle. The
holes would crack out under stress.

In fresh aluminum, use NoAlox or some other type of antenna grease. I find
a little extra Vaseline in the mix helps. The idea is not to mess things
up, but just rub enough in to seal the pores of the metal.

A twinlead J-pole in a PVC pipe works well for this. Our club had one
on a post stabbed into the ground when we needed talk-in at the BBQ's.

I think I've read that you should avoid using steel wool. Tiny pieces of
the steel become embedded in the aluminium. The 'dissimilar metal'
effect soon causes worse corrosion. It is best to use a non-metallic
scoring pad.

> Back then, I preferred GE radios:

Back in the day we were radio techs and weight lifters!

I used both. I had Pre-Progs and Progs. Both were good for keeping warm and digging out of the snow, but the MHT motracs were extremely easy to duplex, bullet proof and had excellent audio. With 110 watts VHF and the optional preamp for .12uv for 20dbq, that radio talked like no other I have owned before or since, and I could do it parked at a jam packed radio site. I ran a UHF 35 watt radio, duplexed, to access a high level remote base system with an autopatch. We had wide area flat rate dialing and I had a switch on my WE TT pad to key the radio continuously. A resistor across the relay and a small cavity for the RX and it sounded better than the IMTS system. I never graduated to Micor for a mobile because it could cost you $500 just to fill up a 12 channel mobile. I was using a duplexed 73MHT up to 5 years ago because I always wanted to monitor that frequency and had little trouble as NCS.

IMNSHO the Micor and MastrII have yet to be improved upon for performance and practicality for a repeater.

OH - the point was the coupling in the PA tube would allow you to match directly to 75 ohm.

I agree with the NoAlox but I reserve comment about drilling out the holes until you clean it first to see if it needs drilling out.
You can pick up NoAlox, or Penetrox in the electrical dept of Lowes or Home Depot, or at an Electrical Supply house like Graybar. It is used by electricians when making electrical connections with Aluminum wire. It contains an abrasive to cut through the oxide, and the grease to coat the aluminum and keep O2 from it.

> ok, give us your equations. what EXACTLY have you done to Gauss? NO HAND
> WAVING, write the equations!
No David there is no point going down that path again. Me giving you
an equation
would only add more problems. You surely must be aware of an
arbritary border
format where the contents are in equilibrium, why not play with the
Gaussian law of statics
and learn how such a field becomes handy. Then you change it to a
dynamic field with the addition
of radiators while maintaining equilibrium and then subject everything
to a time varying field.
When you do this for your self it becomes more meaningfull to the user
but you have a real problem that you have to sort out
before you play with any of the electrical laws. You have to review
history to convince yourself that all the masters involved in physics
made the proviso that equilibrium MUST exist for the laws to be valid.
They made this proviso based on the reasoning that our Universe is in
a state of equilibrium and later that every action has an equal and
opposite reaction (Newton) If you do not agree with these principles
then the use of a arbitrary border for a mathematical solution is not
valid.
As far as Dr Davis of MIT who is working for the space agency, he did
everything that was required of him and then left. Several times he
came back to help out members of the group with respect to the
mathematics but it was plain that the group did not welcome his
presence. The private e mail I received from him gave me a lot of
confidence in my findings. What I find exciting is that galactic
particles are finding their way from the Sun to Earth which gives
mechanical content to the subject of radiation as opposed to the
prevailing theory of waves. To me this is more far reaching than just
radiation as it also gives other cycles to these same particles with
an affinity to water and other diamagnetic substances which gives it a
firm connection to storms and tornadoes as well as rotating sea areas
along with tides, all of which involved the four forces of the
Universe which Einstein correctly fore saw radiation as the key for

forward movement in understanding of Classical Physics. I consider
myself very fortunate when going back to the Gaussian fields and
applying a broader mathematic front to his work which he may have well
did for himself if he stayed in the field. Doing this provided so many
clues with respect to radiation and how it is produced which produced
connections to other known phenomina which was well known but now how
a dotted line connection to other things that are well established
such that more extensive research was not required which can be very
difficult to those not involved in the academic field;. For me the
jigsaw is now completed and as history shows change takes a long while
to be accepted certainly by those in academia
but for me it doesn't matter as I feel very smug and fortunate with my
findings which contempt by others cannot eradicate.
Enuff said

These compounds actually contain irregular particles of zinc which is a superior metal for contact with aluminum. Hal is otherwise correct.

Ian is also correct about avoiding the use of steel wool with aluminum. Invariably, you will get fine steel particles imbedded in the aluminum which will promote the corrosion of the aluminum.

If screws go through the holes in the aluminum, use heavily galvanized hardware to minimize future corrosion. For steel screws, heavy cadmium plating is ideal, but due to its toxicity, is getting more difficult to find.

Time is up. I'm back from the dirt pile. Let the games continue.
What blows my mind is why a certain whiny Englishman who
moved to the land of Obama, refuses to do his own homework to
show the world.
Why would I want to do work on your dinky dummy load on a stick?
Why would I even *need* to do your work? After all, all is known
regarding antennas according to you. So you should already know
all the details of this mathematical endeavor, and should be prepared
to release them to the unwashed stinky masses.

> It blows my mind when a ham with a doctorate comes along and supplies
> the mathematical proof and the math is denied
> by the guru's on this newsgroup.

Why do you keep lying about the doktor. We all know he didn't provide
any math. If your advanced age has made this hard for you to recall,
I can provide the links to the original thread, which I have already
done
before. Maybe even two or three times. :/

> It blows my mind when hams state a conductor must be straight when
> they use helicals in so many places yet despite the denials
> they will not do the math for themselves but continue to ask me
> endless questions so they can continue arguements.

What math might I need to answer whatever question you might
have about coils? You already know everything about antennas,
so why bug us about it?

> Then they deny I have such an antenna and an Aussie who obviously
> likes to bet offered a wager of what was it $1000 US ?
> and nobody took him up on the wager.

I have no idea what you are blabbering about. I know you supposedly
sent one of your designs to another ham on this group for a test
run. We have never heard a single peep as to the results of this
test drive. What say, Mr. Stinky?

> Then there are computor programs
> that push aside Yagi antennas in favor of those
> in equilibrium which support what I have found and these programs are

> designed around Maxwell who is now arpparently losing favor with hams
> tho professionals cling to it dearly.

Must be a strong program to be able to push around yagi antennas.
Well, I suppose if the yagi was built for 1.2 ghz, it would be
fairly
easy to push aside. But I suspect it would strain mightily to
push around a HF tri-bander..

>I have no problem with Guru's
> disagreeing with me but I did expect a morsel or a small challenge
> in at least one area other than look up the dictionary for them to get
> the definition of equilibrium.

I *know* how the rest of the world describes equilibrium. What
I want to know is how *you* apply this term to antenna theory.
Of course, I'm not going to hold my breath waiting for you to
provide this simple answer.
All you want to do is whine, piss, and moan about the sorry
state of the antenna world as you know it.

>And now we have a man who has written a
> book
> and preferes to tout this piece of trash rather than do the math with
> respect to the radiation all on the basis that what he believes is in
> a book that he wrote so it must be authentic.

What are you whining about now? I know nothing of your man, and
his book. I've been busy playing in the dirt. I guess I missed the
memo...

> David take note when
> your book comes out it may spawn a new science to rival classical
> physics.

I wouldn't be holding your breath.

>It blows my mind that we have threads that break the thousand
> mark on reflections or swr and then get repeated again and again
> because of disagreements on the substance

Your mind is going to explode if you keep this up. !!!BOOM!!!
Blood and brain matter flying all about.. Another one bites the
dust..

> Now he is toting a later
> edition hoping to collect some money from hams.

Money is good. And I can do the math when it comes to $$$.

> Give me a break since
> he will not do the math that I speak of probably because he can't
> handle the difference in units between Gauss and Maxwell.

When are *you* going to do the math?

>You know
> when OBAMA
> wins the election on Tuesday hams will unite and declare McCAIN the
> winner

I hope so. Obama sucks so hard, he's likely to implode before he gets
in office. Of course, you'll probably vote for the sorry socialist sum-
bitch,
if you haven't already.. :(
I bet he won't do the math for you either. Sure, he'll tell you
whatever
you want to hear at the moment, but at the end of the day, all you
will have is a dummy load on stick legs. Maybe we should have your
antenna do some squats. :/

It happens but it's not supposed to. A standard rule is that an Aegis ship needs to "sector out" other vessels in company when they are within a specified distance -- I forget the number. Among the more vulnerable equipments are the EW receivers.

The AN/SPY-1 sends a pseudo-random pulse train. When you hear one on a suitable receiver, it sounds like corn popping. No joke.

Good question.

Art`s full wavelength of wire is rolled up so its individual elements aren`t strung up to fully reinforce each other`s fields. Resistance loss of the elements adds even when rolled up.

Art wrote:
"What blows my mind John there is nobody willing to do the math with respect to my extension of GAUSS."

Who needs it?

Terman`s 1955 opus says on page 864:
"Radio waves represent electrical energy that has escaped into free space: they are described in detail in Sec. 1-1. Radio waves are produced to some extent whenever a wire in open space carries a high-frequency current. The laws governing such radiation are obtained by using Maxwell`s equations to express the fields associated with the wire: when this is done there is found to be a component, termed the radiated field, having a strength that varies inversely with distance."

Best regards, Richard Harrison, KB5WZI

Well Richard I don't go along with that unless the definition of a
wave is made clear.
Some see a wave likened to a part of a cobwebb m oving in the
atmosphere. Other see a wave as a group of particles
unconnected but moving in unison with other particles thru the
atmosphere. I go with the particle aproach in a counter gravity
flight.
Until. a good definition of a wave comes along and how such is
constituted;
As far as doing all the work for me the work has all been done and
each assertion is backed up by existing modern practices such that no
more proof is required. If people want to ignore science let them
believe that the World is flat but I can't expect the like of Mark to
follow such a trail as he readily admits
to not completing high school or for that matter people who consider

that all education has been completed and thus all is known,.
Fortunately many hams are continueing to experiment in search of the holy grail where others wish to continue as just talking heads.
Termnans definition quoted above is not definitive with respect to radiation in any way and it is well recognised that radiation is not known in all its aspects.
What is known is that there are four fources involved all of which are accounted for in Maxwell's mathematics but not fully explained in a scientific account
and that includes the so called definition that Terman put forward in the absense of fuul knoweledge of radiation.
Regards
Art

I have used Radio Works Carolina Windom, CW80 couple of years. After transmitting RTTY couple of minutes around 7-800 watts, antenna went dead.. Infinite SWR on all bands.. I think Balun was dead.. I want to replace more bigger balun for high power, which manufacture's balun is good for CW80?? Is it a 4:1 or 6:1?? I would like to homebrew if there is a step by step guideline..
Thanks for your help..

I hope it is a good flight. Of course, with the recent economic
downturn, I imagine in-flight meals are out.
I heard they now offer a cup of water and a fig neutrino.

> As far as doing all the work for me the work has all been done and
> each assertion is backed up by existing modern practices such that no
> more proof is required.

Well, then WTF are you doing here whining about it?
Art, you are just plain full of crap. If the work had been done,
you would be offering it as evidence.
But all you do is hand wave various levels of bafflegab.

>If people want to ignore science let them
> believe that the World is flat but I can't expect the like of Mark to
> follow such a trail as he readily admits
> to not completing high school or for that matter people who consider
> that all education has been completed and thus all is known,.

Well, it's obvious that your education has led you astray.
You can't spell worth a crap, your ideas about science
border on lunacy. And to top it off, you probably voted for
Obama. :(
And you want to whine about my level of education?
I'm sure this is news to you, but they don't offer antenna
theory in high school. So it wouldn't make a rats ass
if I finished high school or not. I would still have to study
antenna theory either at a later school, or on my own.
I choose to do such study on my own time.

My home schooling appears to be superior to your
version, being I spell slightly better than you do, and
when I talk about antenna theory, people don't constantly
jump down my back telling me I'm insane.
I'm not even corrected very often, and I'm sure they would

if I was off in outer space as far as theory or even
details of whatever antenna talk I enter into.
A fairly nit picky bunch you have around here.
They don't suffer fools very well.

On the other hand, you can't make one post without
causing extreme controversy.
Your idea of science is to conjure up various degrees
of bafflegab, and then blame everyone else for not doing
your "work" when the controversy starts up.

> Fortunately many hams are continueing to experiment in search of the
> holy grail where others wish to continue as just talking heads.

What is a holy grail antenna? I know what a talking head is.
I see them on the tube every day.
On the other hand, all I see you do is talk out your ass.
A talking ass. Kind of reminds me of Mr. Ed, with a
twist.

> Termnans definition quoted above is not definitive with respect to

Art, I've got news for you. Terman probably forgot more about
radiation than you know in totality. I think Richards book was
printed in about 1955, and it's still fairly relevant.
You on the other hand... :/

4080. Anyone out there using a HAZER on their Rohn 25 Tower?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-04 23:25:55 UTC
From: Jim <nospam@nospam.com>
Message-ID: <c6m1h4lbflh5fhfvc7jm4niqp4t00gmmcp@4ax.com>
Source record: 20454

I have been thinking of purchasing a HAZER tram system, but after
reading all the reviews all over the web I'm kind of leery.

Anyone out there using one? If so, I would like to start a dialog or
swap E-Mail or call you on phone to find which model you are using,
and what problems you have had with the system. The reviews seem
to go 10 to 1 against the Hazer, recommending a crank up tower....

I would appreciate any comments and recommendations and
in general should I waste my money on the thing or does it work
as advertised?

This one single action, and this article on it,
http://news.cnet.com/8301-1035_3-10082505-94.html, pretty much, puts the
final nail in amateur radios coffin.

The main reason?; it makes amateur radio seem like a childs toy/play in
comparison to the communications which are shortly to lay at each and
every citizens finger tips, and secure communications at that.

Only the proper funeral for amateur radio lays in the future, and that
will, most likely, even be skipped--except for the odd article lamenting
its' death ... I think the importance of all this will be missed by a
good 99.9999999% of amateurs ...

Technology is a double edged sword, but one which forever prods us on a
forward path.

So, let's get a freq list together and start planning those antennas for
our cell phones, hand-helds and laptops!

Regards,
JS

Art, the following should address your concerns with respect
to Gauss's law.

I maintain the web site for the "Night Train Express" net on
75 m, and have added a page to this web site
concerning Gauss etc. There are two pages copied from
a text book. Note that the third of Maxwell's equation is
Gauss's Law.

Link at: http://www3.telus.net/nighttrainexpress/maxwell_1.htm
Click on "Next" for the 2nd page of math showing the development
of the wave equation.

Well Richard I don't go along with that unless the definition of a
wave is made clear.
Some see a wave likened to a part of a cobwebb m oving in the
atmosphere. Other see a wave as a group of particles
unconnected but moving in unison with other particles thru the
atmosphere. I go with the particle aproach in a counter gravity
flight.
Until. a good definition of a wave comes along and how such is
constituted;
As far as doing all the work for me the work has all been done and
each assertion is backed up by existing modern practices such that no
more proof is required. If people want to ignore science let them
believe that the World is flat but I can't expect the like of Mark to

follow such a trail as he readily admits
to not completing high school or for that matter people who consider
that all education has been completed and thus all is known,.
Fortunately many hams are continueing to experiment in search of the
holy grail where others wish to continue as just talking heads.
Termnans definition quoted above is not definitive with respect to
radiation in any way and it is well recognised that radiation is not
known in all its aspects.
What is known is that there are four fources involved all of which are
accounted for in Maxwell's mathematics but not fully explained in a
scientific account
and that includes the so called definition that Terman put forward in
the absense of fuul knoweledge of radiation.
Regards
Art

I appreciate higher education, Art. But not all higher education needs to be obtained at college or university.

After all, if one reads the same books outside of an organized curriculum and if one truly loves the pursuit of knowledge, is it not possible for one to further ones knowledge without completing organized/formal schemes of formal education? IIRC, some of our most important scientific discoveries were made by "uneducated" individuals. I feel that too much emphasis is placed upon having credentials in this world, not that I would not like to have a degree or two of my own to proudly display on the wall.

I don't believe in waves moving through ether. I believe there is a
field around a radiator, exactly like the glow around a light bulb.

4092. FS: AT-271 Fishing Pole Antenna. ..Miltary Collapsible Antenna

Newsgroup: rec.radio.amateur.antenna

Cross-posted to: rec.radio.amateur.antenna,rec.radio.swap

Have available the AT-271 Military Collabsible Antenna.... $30 USD Plus Shipping

This portable antenna can be used for the top section of a Vertical Antenna OR Horizontal elements for an Antenna System such as the Buddipole tm ..... A Great QRP / Portable Antenna weighs only 400 Grams [14 Oz] and measures 104" extended yet only 14" long when folded.
The construction is the same as is used for sectional fishing poles. Each of the 8 hollow tubular metal sections has a plug one one end and a socket on the other end. All the sections are connected by a string made of either a cloth or metal cord. At the bottom of the base element there's a spring inside the tube to tension the cord. Some units may use an elastic shock-cord material. This way all the elements are kept in order when they are disconnected from each other and are held together when assembled into a 104" [8.6 Ft] long antenna. When the elements are folded or disassembled the package is only 14 inches long.
The base has a male 3/8-24 thread which is the same as is used on most Ham Radio and CB antennas. Some sort of spring base could be used when this antenna is used because the hollow antenna elements will "fold" if too much force is applied to them.
These units are in Like New Condition.. Sold AS-IS but will not be DOA.
Have access to more...ASK!

Sorry, Dave. I did not write that text.

Allegedly, scientists have determined that the very foundation of our
universe is made of something that they call "quantum foam". Tiny sub
particles that pop into and then out of existence. To me, this is just
another way of saying "the aether".

Ed, I agree with you 100% but if you are going to debate a subject
then one stands on his knoweledge base
without resorting to slirs. In a debate both positions are put on the
table for debate.
We are long gone from the days that those who challenge old ideas are
pushed aside purely on the volume of jeers
without any evidence what ever. Mark cannot debate the subject on its
technical merits however he can mount an assault
on any messenger based on emotions, he certainly is not equiped to go
thru the higher math of Maxwell and Gauss.
This does not exclude him from any discussion but to mount a personal
assault in the place of knoweledge just gives exposure
to what a person he really is.. On the subject of antennas I have put
thru a theory where a particular antenna is produced.

Antennas produced in the past have been torn apart on its merits thro
out ham radio history but only after study and it is this study that I
am looking for.
As yet nothing that I have put forward has been scientifically
refutted not that I wish for that but I do relish a challenge
Regards
Art

David
Nothing wrong with that as we are looking at the exchange of energy
as with a tank circuit, I don't think there is any disagreement with
at, it is where the subject
of communication fits in.
Observation shows that communication density varies with the state of
the Sun and scientists
have recognised particles on Earth that comes from the Sun. We also
know that communication exists in a straight line
so one must determine how such a thing can be created. We all know
there are four forces at work in our Universe
so it is essential that they are fully understood when we study
radiation such that existing facts are corroborated.
So David now you have established that there is a sort of glow in your
mind around a antenna you have only established a possible starting
point
of your study. I have put forward a replication of radiation based on
scrap sorting procedures that match the tank circuit phenomina and
applied it to the subject of radiation where I account for all the
four forces where straight line projection is maintained so why is
this such a problem to hams?
Regards
Art

Art wrote:
"Well Richard I don`t go along with that unless the definition of a wave is made clear."

We deal with sinusoidal waves because all other shapes can be nade from combinations of these.

Particle aspects of radiation come to the fore only when radiation interaxts with matter.

Physics tells us a particle that moves with constant momentum in a straight line according to Newton`s first law (inertia statement) has wave motion, according to the "de Broglie hypothesis". Lambda = Planck`s constant / momentum.

The wave aspect of EM radiation is used as a model to make the phenomenon intelligible in terms of familiar laws and events of our everyday, large-scale world.

The 3rd edition of Kraus` "Antennas" says on page 904:
"They (computer program designers) could develop software to simulate the performance of antennas. In general, these techniques either numerically solve Maxwell`s equations by descretizing the problem using integral techniques, such as Moment Methods (MoM) as discussed in Sec.14-11, or differential technuques, such as finite elements or finite difference-time domain."

Maxwell gave us everything we need.

Best regards, Richard Harrison, KB5WZI

How can one debate an issue when the one offering
the new theory refuses to answer any questions posed to him?
And if I run across some math I can't handle, I can surely find
someone who can. No one is going to be able to know
everything, and that includes you.
It seems to me you are not equipped to handle the math
yourself. You sure haven't offered any at all. Zero.Nada. Zilch.
So how would you know if I can handle the math or not?
You haven't offered any to inspect.
And neither did the Doktor you constantly bring up. Not a bit.

> This does not exclude him from any discussion but to mount a personal
> assault in the place of knoweledge just gives exposure
> to what a person he really is..

You are the one that started the personal assaults a long time
ago. You've had your knickers in a twist ever since I proved
your "loophole" antenna did not work as you claimed and
it's all gone downhill since then.
And that was a long time ago.
You are the only one that seems to be worried about my
level of education. No one else seems to care a whit.
If I'm such an ignorant dumbass as you claim, why did
it only take me about 30 minutes to disprove your "loophole"
antenna theory. You know, the dipole fed with a version of
a T match, with a variable cap that you claimed would
allow you to steer the pattern of the antenna.
A quick modeling of that antenna proved your claims to
be false as far as steering the pattern.
On your behalf, I did prove that the antenna was viable as
far as tuning for each band, but I disproved your claims of
steering the pattern. And I didn't need a spec of math to
do it. What was your response to this modeling?
Nothing at all... :/

Being as I shot that antenna out of the water, you quickly
dropped it, and decided to try other designs.
Very inefficient designs I might add. Of course you

disagree, but you refuse to actually do the real world
tests to prove or disprove these claims.
Instead, you attack the messenger. You whine about
other hams. You whine about England vs the USA.
You just whine. Period. I find it disgusting. Sorry if
that chaps your ass. I really could care less.

What kind of person am I? I'm a person who can't stand a
whiner, that's who I am. And all you do is whine, piss, and
moan about *other* hams that won't do *your* work for you.
On a personal level, you make me sick to my stomach.
If you were any kind of real scientist, you would have done
all this work on your own, and proved or disproved your
theory to *yourself* before braying like a jackass on this
group.

You supposedly gave an antenna to a ham on this group
to inspect and test. Did we ever hear about any results of
this test. Nope. Not a peep. Zero, zilch, nada..
Did he ever report back to you? He sure didn't report back
to us. Of course, you won't reveal if he did or not.

Leads me to believe that my quick analysis of your
antenna was pretty much right on, if you all are afraid
to post the results.
I don't need too much math to smell a turd.
I have enough real world antenna experience to know
what is bunk, and what is the real deal.
I have offered you a sure way out of this mess many
times, but you refuse to listen.
I said, build it and test it! If it actually works, and you
can prove it, your dilemma is over.

But you refuse. You would rather whine, piss, and moan
about all the other hams on the planet.
You claim that most hams think all is known about
antennas. But the only one I hear say that over and over
is *you*.
And to me, it's quite obvious that *you* have a long
ways to go before you could even be close to claiming
you know everything about antennas.
Myself, I know I don't know everything about antennas,
and I don't make claims hinting that I do.
You will notice I don't enter threads which are out of
my expertise. A man has to know his limitations.

> On the subject of antennas I have put
> thru a theory where a particular antenna is produced.

Where is the "produced" antenna? Have you tested it
against a radiator of known performance? Like a dipole?

> Antennas produced in the past have been torn apart on its merits thro
> out ham radio history but only after study and it is this study that I
> am looking for.

Well, I hope you find that study wherever it is hiding and
put it out of it's misery.

> As yet nothing that I have put forward has been scientifically
> refutted not that I wish for that but I do relish a challenge

You wouldn't know how to respond to a challenge if it bit you
in the ass.
You refuse to answer logical questions posed to you. You refuse
to reveal any test results. You refuse to provide any math to
back up your claims. Of course, a horses ass like you will
claim I'm too freakin stupid to make heads or tails of said
math, which may or may not be true.
But like I say, I *do* know plenty of people that can handle
any math that might pose a problem to me, so that claim
is fairly mute.

Anything else you wish to whine or complain about
before you start another thread of useless bafflegab?

Richard you have not come up with anything that contradicts what I
have apothosized, nothing !
\When I mention antannas of a new desighn you say who needs them. When
I say that antennas should be tilted
with respect to the Earth you say BS. When I point to the
coirrelatioin between Gaus statics and Maxwell you remain silent.
Now you bring up Kraus by quoting what he said with respect to
computor programs. I was not happy with computor programs because of
the assumption
that they has about sino soidal current. My studies prove that I was
wrong in that determination. This allows me to review Kraus antennas
to see where he deviated from Maxwell. You point to a computor program
on antennas. Most if not all hams foicus on planar designs where
current is induced
progressively from one element to another in simple electromagnetic
coupling form, that relationship does not supply anything with respect
to radiation.
Programmers put that design as an addition to the program that
revolved around Maxwell you did not work around approximations.
Now I feel it is legitamate to apply the computor programs to my

deductions and Maxwell produces the antenna that I forcast and not the lesser efficient yagi antenna.Same goes for Krauss's work on the helix which like the plana designs are also a approximation. These fact are indisputable if you believe the MOM methods used for computor programs. Now we have the situation where a yagi or the helix is pushed aside by the computor programs in favor of what I have postulated. Now it is YOU who have a problem. I kn ow you do not use computors but it was you that brought the subject up.Computor programs duplicate what I am postilating with more efficient antennas and yet you put computors forward to repudiate what I say.
So what are you going to do now? study computor programming to see how a program based around Maxwellk could provide such incorrect answers, deny the teachings of Maxwell or deny the viability of antenna computor programs which puts ham radio back a generation?
Regards
Art

Look. Ham radio has a problem, a real problem that they refuse to come
to terms with.
Antenna computor programs that have entered ham radio with the full
acceptance
of it's members which takes up a considerable portion of antenna news
does NOT
provide planar antennas as the most efficient antennas based on the
compliance with Maxwell.
This is no small matter for ham radio. We can bury our heads in the
sand or we can
re examine the facts as accepted by science. If adherence to Maxwells
laws provides radiuators
that are more efficient and smaller than the status quo we can ignore
it as Richards states
" we already have a design " or "who needs it"
Now I have shared my findings based on the laws of Maxwell as to why
this is, you need not agree with it
but surely for those who are inquisitive about antennas should be
curious about the parodox that I have exposed.
There are smarter people on this newsgroup whome I have brought this
to their attention so why the silence and the abuse with respect to
these findings
that Einstein pursued in a fruitless effort?

Art

>Hi,
>
>last weekend i bought an Outbacker 1899. I would use a magnet mount
>fpor my car. Is it ok? Do i need a tuner?

There are several issues here.

A really big, hefty mag-mount antenna (one designed specifically for HF mobile antennas) may hold the Outbacker securely enough. These big mag-mounts usually have three separate magnet pads.

I would not depend on a mag-mount of any type to provide adequate electrical grounding for an HF antenna... they don't have enough surface area in the magnet assembly. HF antennas of this type really need to be grounded to the chassis, via a heavy and direct ground lead, in order to achieve acceptable performance. If the ground lead is too long, or has too much inductance or resistance, you may find the antenna very difficult to tune/match and its performance will suffer.

Frankly, I think you may be happier in the long run using a ball mount or a heavy-duty lip mount (the top-of-the-line Comet and Diamond trunk-lip mounts may be strong enough).

I don't generally think that using a tuner with mobile antennas of this type is a good idea... they should be tuned by adjusting the whip length as necessary for the frequency you are using. A tuner mounted right at the base may allow automatic matching on other frequencies in the same band, but the losses (already high) will be even higher than if you tuned the antenna itself.

If you don't go any lower than 14 MHz, it will work
reasonably well - lots of problems below 14 MHz.

No. *You* have the problem, not ham radio as a group.

I don't fully accept *all* results obtained through the use of
antenna
programs. There are a few cases where the programs have problems.
Fortunately, most of these are known, and if you really understand
what you are trying to model, it's usually fairly obvious if something
is in error.

> This is no small matter for ham radio. We can bury our heads in the

You haven't exposed anything except a bunch of baffle gab.

> There are smarter people on this newsgroup whome I have brought this
> to their attention so why the silence and the abuse with respect to
> these findings
> that Einstein pursued in a fruitless effort?

Well, obviously they don't seem to agree with your theories.
And who could blame them when the only "proof" offered is
conjured up baffle gab.
The ball is totally in your court. Either do the testing and
prove your theory, or accept the failure.
I know I'm not going to do any work on it. I don't like
compromised inefficient antennas. So there is no incentive
whatsoever for me to waste my energy on it when it's sure
to be less effective than what I use at present.

4107. American Tower parts - Be prepared for GRIEF

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-05 20:35:22 UTC
From: Jim <nospam@nospam.com>
Message-ID: <lsv3h45qpnqbiljnt3mthv1a5ab6pbeiu8@4ax.com>
Source record: 20481

FYI:

I bought some new parts for my Rohn 25 from OldTowerGuy on Ebay, and one was a hinged base. Well, it took me almost a day to get the 3 pins on the base into the legs in the tower. When I wrote them they told me that Rohn had changed plants recently and they were not keeping their dimensions up to spec. Only thing wrong with this excuse is that this was a brand new section that had been in storage for many years, unused (I had 3 of them). I tried to get the thing on several new and used sections, same exact problem.

Then after using a car scissors jack and axe and baseball bat to finally get the 3 pins into the base, he holes on one leg would not line up, no matter what. I got bolts into holes on two legs, but the other two were off in two dimensions. They were too far into the leg for holes to line up, and then on the axis they were off too. It took two of us some time with car scissors jack wedged between crossarm and base plate to force the two holes to line up vertically, but they were still not lined up axially. We tried all kinds of drifts, screwdrivers, and so forth, and was about to redrill the hole, when we were finally able to force one of the bolts through the leg, then the last one lined up after beating it in with a baseball bat.

Luckily I decided to try to see how the hinge worked. I did notice that even though the holes for the hinged
portsions are for 1/2 inch bolts, they shipped the thing with all 3/8" bolts. I went to Fastners store and bought stainless 7/16" bolts to allow for a bit of slack, and guess what? The thing is so far out of alignment that it would not go down to flat position so you could put the
two captive bolts in to hold the tower upright. The fartherst you can get the tower down is at about a 5 or 10 degree angle.

I'm hoping they take it back but with EBAY you never know what will happen or what you will lose.

Caveat Emptor - I'm sticking with Rohn from now on.

Richard says: Hooray! Richard does not discourage novelty or the computer which is a most useful tool. Show us the novelty and the data.

Art`s rant reminds me of an offhand remark by Jerry Chinski, Chief Engineer of KXYZ when I worked there in 1949. It was not directed at me when Jerry said: "You can have the best equipment in the world but if knuckleheads are operating it, the product is likely useless."

Antenna modeling is well tested and accepted. If the computer operator is a knucklehead, its output is likely useless (GIGO). The operator likely needs help to get useful output. But, some operators blame the system not their own ineptitude.

Many participants in this newsgroup use EZNEC to get good results when evaluating prospective antennas. I`m sure some blame the system when it doesn`t produce the desired results. I`d call them Chinski-ites.

My 20th edition of "The ARRL Antenna Book" includes a CD-ROM of the entire book. Chapter 8 is "Phased Array Techniques" , written by the EZNEC man, Roy W. Lewallen, W7EL. It is full of practical information in print for all to see and criticize. Last line in the book is: We would appreciate any feedback or bug reports you might have.

If Art would subject his data to such scrutiny, he might get more cheers and fewer jeers.

Best regards, Richard Harrison, KB5WZI

Ok Richard so I am inept, let us leave it at that. There are many
experts and guru's on this newsgroup
who pretty much agree with you and not one has come forward to refute
some of the things that have been stated against what I proffer
So I will assume that the program is accepted for Yagi' but not for
radiators in equilibrium.
All this is not unusual a lot of things that were found out were
delayed from the public because of people just couldn';t take change.

Those who do not understand the rules of science with respect to
radiators say it is bafflegab because they don't understand the
sciences.
So I will let it go at that and assume that I am the one out of step.
You and others have made your point and there is no such thing than a
better antenna than the Yagi and that all is known is about antennas
and nothing that is not printed in a book is acceptable to radio hams.
I get the message and that should make every one happy

4114. WHEEL STATIC ONLY ON SOME PATCHES OF PAVEMENT? WHY?

WHEEL STATIC ONLY ON SOME PATCHES OF PAVEMENT? WHY?
With the financial mess, I have started to listen to AM radio in the car on the way to and from work for the past few weeks and I've noticed some random static at certain locations. At first I attributed this to some power line noise. Bit it didn't really sound like 60 Hz buzz hash, it was more random popcorn like but I know power lines can blow around in the wind and have strange discharges so I didn't think too much of it for a while. But after a few days I noticed that the static is there only when the car is moving. OK, so its wheel static. Static electricity from the wheels or brakes or something. OK that's not unusual either. But it is the combination that has me curious. This static only occurs when the car is moving and it only occurs at certain repeatable locations on my drive. Everyday when I turn the corner from X to Y, I get the static as the car is moving, but not when stopped at the same corner. And I never get the static when turning the corner from A to B. If it was power line, stopping the car wouldn't stop the static. If it is wheel static, why does it not happen all the time and happen only at certain locations. It seems as if these certain locations have something special about the pavement or the water content of the soil or something. None of that seems likely to me though, I see nothing changing in the pavement as I drive from an area of static to an area of non-static. It is not related to stepping on the brake or gas or shifting gears or going over bumps or any other aspect of the car that I can tell other than it's speed down the road.
As an experiment, I attached a drag wire under the car. The wire drags on the ground to discharge any static build up the car. This made no difference. Another clue, we've had no rain here in a while. The static all stops during wet weather. Also I am in the Philadelphia area and the AM station is in the New York area so it is on the weak side.
I've been a ham for over 30 years and I have a lot of experience with EMI, but this one has me scratching my head. The wheel static changes repeatably in different locations for no apparent reason. It's got to be something to do with the pavement. Anybody have any experience with this?

Mark

You got your ideas by reading headstones?

>I get the message

Somehow I doubt that. You sound like today's concession speach as a
warm up for the next campaign cycle.

Art, if you were running for political office, your idea shelf life
would equal Lyndon Larouche's.

My guess is different lengths/types/orientation of rebar in the roadbed.
